Analysis of a Mixed Strategy for Multiple Relay Networks

Peter Rost, *Student Member, IEEE,* and Gerhard Fettweis, *Senior Member, IEEE*

Abstract

In their landmark paper Cover and El Gamal proposed different coding strategies for the relay channel with a single relay supporting a communication pair. These strategies are the *decode-and-forward* and *compress-and-forward* approach, as well as a general lower bound on the capacity of a relay network which relies on the mixed application of the previous two strategies. So far, only parts of their work - the decode-and-forward and the compress-and-forward strategy - have been applied to networks with multiple relays.

This paper derives a mixed strategy for multiple relay networks using a combined approach of partial decode-and-forward with $N+1$ levels and the ideas of successive refinement with different side information at the receivers. After describing the protocol structure, we present the achievable rates for the discrete memoryless relay channel as well as Gaussian multiple relay networks. Using these results we compare the mixed strategy with some special cases, e. g., multilevel decode-and-forward, distributed compress-and-forward and a mixed approach where one relay node operates in decode-and-forward and the other in compress-and-forward mode.

Relay network, discrete memoryless relay channel, Gaussian relay channel, successive refinement with unstructured side information, degraded message set broadcast channel

I. INTRODUCTION

The growing popularity of mobile communications systems, sensor networks as well as ad hoc networks draws an increased activity in the field of network information theory and relaying in particular. The basic idea of relaying [1], [2] is to support a communication pair using additional radios. Two basic coding strategies for the one-relay case were proposed by Cover and El Gamal in [3]: *decode-and-forward* (DF) and *compress-and-forward* (CF); both still serve as basic building blocks of recent protocols.

Furthermore, [3, Theorem 7] provides a general lower bound on the capacity for the one-relay case which can be achieved using a combination of DF and CF. More specifically, the source message is divided into two parts: U_s^1, which is decoded by the relay node, and U_s^2, which can only be decoded if U_s^1 is known. As illustrated in Fig.

Manuscript submitted February 2, 2008.

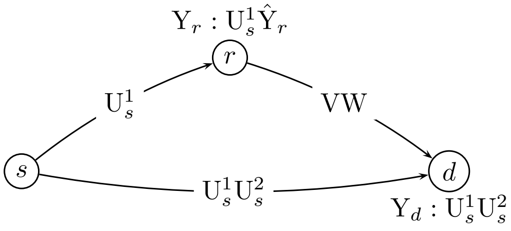

Fig. 1. Information flow of the general lower bound for the one-relay case.

1, the relay terminal r decodes U_s^1 and selects a message V using the random binning procedure introduced in [4]. Since the source node knows this mapping it also knows the message V and can support the relay transmitting V. The relay further uses $\hat{Y}_r$ to quantize its uncertainty about U_s^2 in its channel output Y_r and selects a message W depending on this quantization. The destination node d decodes V and uses this additional information to decode U_s^1. Using the message W and the correlation between the relay and destination channel output, the destination decodes the quantization $\hat{Y}_r$ (a strategy similar to Wyner-Ziv coding [5]). With the quantized channel output of the relay and its own channel output, the destination finally decodes the second source message U_s^2.

A. *Motivation*

More recent work on relaying concentrated on the analysis of networks with multiple relays: among others, Gupta and Kumar derived in [6] bounds on the capacity of ad-hoc networks without cooperation between individual nodes. Again, Gupta and Kumar generalized in [7] the DF approach to a multilevel relaying scenario where each node decodes the full source message and uses irregular encoding. Later, Xie and Kumar proposed in [8], [9] a DF strategy based on regular encoding and successive decoding, which in general achieves higher rates than the proposal in [7]. Besides, Kramer *et al.* [10] derived different DF or CF based strategies for a variety of different relay networks such as the multiple access and broadcast relay channel.

Except for [10], these approaches regard coding schemes operating either in DF or CF mode. In [10, Theorem 4] a mixed approach was presented where the network consists of both CF and DF nodes. Furthermore, in [10, Theorem 5] a specific mixed protocol for two relays was presented. The motivation of this work is the development of a framework generalizing the previously mentioned approaches such that the protocol with the best performance or lowest complexity can be found for a specific network setup. One way is to derive different protocols and compare them to each other which obviously is not an efficient solution. Therefore, we follow in this work a similar approach as [3, Theorem 7] and derive a strategy which is able to specialize to different protocols depending on the actual network setup. This might be of special interest for instance in ad-hoc networks or mobile communications systems where it is necessary to use low complex protocols. Hence, it is beneficial to support a small number of low complex protocols which provide the best performance in specific situations instead of using one high-complex protocol.

B. *Contribution and outline of this work*

In this work we derive such a mixed strategy which generalizes the previously mentioned approaches. The main idea is to divide the source message in $N+1$ partial messages (where N denotes the number of relays in the network). Each relay level $l \in [1;N]$ decodes the first l partial messages and quantizes the remaining uncertainty in its own channel output. This quantization is then communicated in different successive refinement steps to the next levels $l' > l$, which use this quantization to decode the partial source messages U_s^k with $l' \geq k > l$.

In Section II we define the considered network model as well as used notations before we describe in Section III the protocol in detail and show its commonalities with the problem of successive refinement with unstructured side information at the receivers as well as the degraded message broadcast channel. We further derive in this section the achievable rates for the discrete memoryless relay channel before we apply these results to a wireless model in Section IV.

II. SYSTEM MODEL, NOTATIONS AND DEFINITIONS

In the following we will use non-italic uppercase letters X to denote random variables, non-italic lowercase letters x to denote events of a random variable and italic letters (N or n) are used to denote real or complex-valued scalars. Ordered sets are denoted by $\mathcal{X}$, the cardinality of an ordered set is denoted by $\|\mathcal{X}\|$ and $[b;b+k]$ is used to denote the ordered set of numbers $(b, b+1, \cdots, b+k)$. With $\mathrm{X} \overset{n}{\sim} p_{\mathrm{X}|\mathrm{Y}}(x|y)$ we denote the random n-length sequence $\{\mathrm{X}[t]\}_{t=1}^n$ whose elements $X[t] \in \mathcal{X}$ are i.i.d. distributed according to some pdf $p_{\mathrm{X}|\mathrm{Y}}(x|y)$ (in the following we will drop the subscripts if it clear from the context), i. e., $p(\mathrm{x}|y) = \prod_{t=1}^n p(\mathrm{x}[t]|y[t])$. Let X_k be a random variable parameterized using k then $\mathrm{X}_\mathcal{C}$ denotes the vector of all X_k with $k \in \mathcal{C}$ (this applies similarly to sets of events). Matrices are denoted by boldface uppercase letters $\mathbf{K}$ and the i-th row and j-th column of matrix $\mathbf{K}$ is denoted by $[\mathbf{K}]_{i,j}$.

This paper considers a network of $N+2$ nodes: the source node $s=0$, the set of N relays $t \in \mathcal{R} := [1;N]$ and the destination node $d = N+1$. The discrete memoryless relay channel is defined by the conditional pdf $p\left(\mathrm{y}_\mathcal{R}, \mathrm{y}_d | \mathrm{x}_s, \mathrm{x}_\mathcal{R}\right)$ over all possible channel inputs $(\mathrm{x}_1, \cdots, \mathrm{x}_N, \mathrm{x}_s) \in \mathcal{X}_1 \times \cdots \mathcal{X}_N \times \mathcal{X}_s$ and channel outputs $(\mathrm{y}_1, \cdots, \mathrm{y}_N, \mathrm{y}_d) \in \mathcal{Y}_1 \times \cdots \mathcal{Y}_N \times \mathcal{Y}_d$ with $\mathcal{X}_i$ and $\mathcal{Y}_j$ denoting the input and output alphabets.

We will use in the following $(\mathrm{x}^n, \mathrm{y}^n) \in \mathcal{A}_\epsilon^{*(n)}(\mathrm{X}, \mathrm{Y})$ to indicate that the n-length sequence tupel $(\mathrm{x}^n, \mathrm{y}^n) \in \mathcal{X}^n \times \mathcal{Y}^n$ is ϵ-strongly typical with respect to the joint pdf $p(\mathrm{x}, \mathrm{y})$ where we abbreviate $\mathcal{A}_\epsilon^{*(n)}(\mathrm{X}, \mathrm{Y})$ in the following by $\mathcal{A}_\epsilon^{*(n)}$ if it is clear from the context [11, Ch. 13.6]. Let $\pi(\mathcal{X})$ be the set of all permutations of a set $\mathcal{X}$. The source chooses an ordering $o_s \in \pi([1;N+1])$ where $o_s(l)$ denotes the l-th element of o_s and $o_s(N+1) = N+1$. For the sake of readability we abbreviate in the following $\mathrm{Y}_{o_s(l)}$ by Y_l and the relay node $o_s(l)$ by l or as the *l-th level*. Besides, each relay l introduces an ordering $o_l \in \pi([l+1;N+1])$ where $o_l(i)$ indicates node $o_s(o_l(i))$. We further use in the following the function ϕ_l to denote the inverse of o_l, i. e., $o_l(\phi_l(i)) = i$.

Remark 1: In comparison to [7] we do not consider any grouping approach where multiple relays are operating simultaneously in one group. The qualitative result of this work would not change by grouping nodes but only makes the analysis more involved.

Definition 1: A $(2^{nR_s^1}, 2^{nR_s^2}, \ldots, 2^{nR_s^{N+1}}, n, \lambda_n)$ code for the previously described system model consists of the following

- A set of equally probable indices $\mathcal{W} = [1; 2^{nR}]$ where $R \leq \sum_{k=1}^{N+1} R_s^k$ and the corresponding r.v. W over $\mathcal{W}$.
- The source encoding function $f_0 : [1; 2^{nR}] \rightarrow \mathcal{X}_s^n$.
- The relay encoding functions $f_{l;b} : \mathcal{Y}_l^{[1;b-1]} \rightarrow \mathcal{X}_l^n$, $l \in [1; N], b \in [1; B]$, such that the n-length sequence $x_l(b)$ in block b is given $x_l(b) = f_{l;b}(y_l(1), \cdots, y_l(b-1))$.
- The decoding function $g : \mathcal{Y}_d^n \rightarrow [1; 2^{nR}]$.
- The maximum probability of error

$$\lambda_n = \max_{w \in \mathcal{W}} \Pr\left\{g(\mathrm{y}_d) \neq w | \mathrm{W} = w\right\}. \tag{1}$$

Definition 2: A rate R is said to be achievable if there exists a sequence of $(2^{nR_s^1}, \ldots, 2^{nR_s^{N+1}}, n, \lambda_n)$ codes with $\sum_{k=1}^{N+1} R_s^k \geq R$ such that $\lambda_n \rightarrow 0$ as $n \rightarrow \infty$.

III. PROTOCOL DESCRIPTION AND ACHIEVABLE RATES

The encoding procedure of the mixed strategy is based on a block Markov superposition coding in B blocks and utilizes the following messages:

- the source messages U_s^k, $k \in [1; N+1]$, with rates R_s^k,
- the support messages V_l^k, $l \in [1; N], k \in [1; l]$, sent by relay level l with rates R_s^k to support the source message U_s^k,
- the quantizations $\hat{\mathrm{Y}}_l^{k'}$, $k' \in [1; M_l]$ with $M_l = N - l + 1$, used to quantize the channel output Y_l in M_l successive refinement steps, and
- the broadcast messages $\mathrm{W}_l^{k'}$ with rates $\hat{R}_l^{k'}$, $k' \in [1; M_l]$, to communicate the quantizations.

The actual channel input X_l at node l is then a deterministic function of the previously mentioned messages. We use further the regular encoding approach presented in [9] as it achieves in general higher rates than the irregular approach proposed in [7]. Consider the following description which explains the encoding and decoding procedure in some arbitrary block $b \in [1; B]$ and is illustrated in Fig. 2 for $N = 2$:

a) ***Encoding in block b:*** The source divides its message into $N+1$ partial messages U_s^k. Furthermore, as the source node knows the mapping of source to relay messages applied at each relay node, it can support the relay messages, e. g., using a coherent transmission.

In block b the relay level l supports the source messages sent in block $b - l$. Hence, assume that it decoded all source messages $\mathrm{U}_s^{[1;l]}$ sent in block $b - l$. Then, it can use the decoded indices to select the corresponding messages from its own codebook. We assume that the relay also correctly decoded all source messages sent in blocks $[b - N; b - l - 1]$. Therefore, relay l knows all messages $\mathrm{V}_{l'}^{[1;l]}$ sent by levels $l' > l$ (as all codebooks were revealed to each relay node) and can support these subsequent levels. Furthermore, the relay node compresses the remaining uncertainty in its channel output by the quantizations $\hat{\mathrm{Y}}_l^{[1;M_l]}$ where node $o_l(k)$ decodes all $\hat{\mathrm{Y}}_l^{[1;k]}$ using the broadcast messages $\mathrm{W}_l^{[1;k]}$ sent by level l.

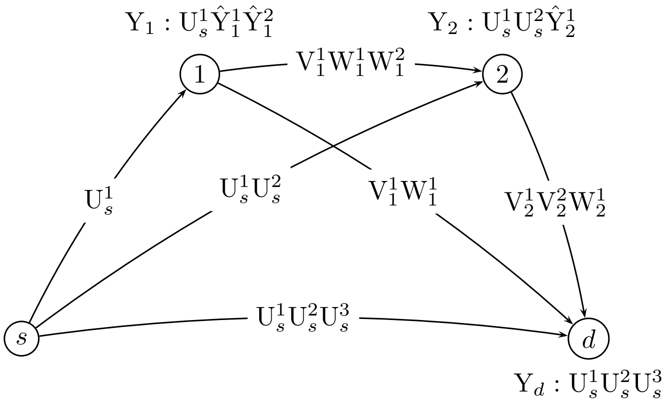

Fig. 2. *Information exchange* of the mixed strategy for $N = 2$.

b) ***Decoding in block b****:* Consider level $l \in [1; N+1]$ and the decoding procedure of the partial source message U_s^k sent in block $b-l+1$. Note that level l decodes the partial messages in ascending order such that when decoding U_s^k all messages used to decode $U_s^{[1;k-1]}$ are known. At first, level l decodes the broadcast messages $W_{k-1}^{[1;\phi_{k-1}(l)]}$ sent by level $k-1$ in block $b-l+k$. Using these messages the relay can decode the quantization $\hat{Y}_{k-1}^{\phi_{k-1}(l)}$ for block $b-l+1$ using its own channel output Y_l as side information.

The decoding of the source messages U_s^k is done by searching for an unique message index such that the source message sent in block $b-l+1$ and all support messages V_{l-m}^k, $m \in [1; l-k]$, sent in block $b-m+1$ are jointly typical with the quantizations $\hat{Y}_{l' \in [1;k-1]}^{\phi_{l'}(l)}$ and the own channel output Y_l in block $b-l+1$.

Remark 2: Before we can proceed we must mention that there two substantially different ways of communicating quantization messages. The first alternative is to communicate quantizations for block $b-l+1$ after decoding all source messages $q_{s,b-l+1}^{[1;l]}$. These quantizations can be used by all subsequent levels to decrease the set of jointly ϵ-typical source messages sent in block $b-l+1$. An alternative is to communicate in block b the quantizations for the channel output $y_l(b-1)$. This has the advantage that these quantizations can be used to decrease the set of jointly ϵ-typical relay messages. Furthermore, using the latter one we only know the messages sent by level $l-1$, hence the quantization is contains significant interference. We decided to use the former alternative as it is easier to generalize and seems to offer more benefits (beside the fact that it is less complex).

c) ***The successive refinement problem****:* The previous description already reveals that the quantization of the relay channel output can be described as a successive refinement problem [12], [13] with unstructured side information at the receivers. Fig. 3 illustrates the successive refinement problem as it emerges in our proposal. The channel output of level l, i. e., Y_l, has to be encoded and transmitted to nodes $o_l(i)$, $i \in [1; M_l]$. At first the channel output is estimated by a quantization $\hat{Y}_l^1$ with rate $\Delta_l^1 = R_{Y_l}(D_l^1)$, where $R_{Y_l}(D)$ is the rate-distortion function for some given distortion D. This estimation needs to be decoded by all nodes $o_l(i)$. Since these nodes can exploit (in general unstructured) side information $Y_{o_l(i)}$, the necessary rate $\hat{R}_l^1 \leq \Delta_l^1$ to describe Y_l at distortion D_l^1 is

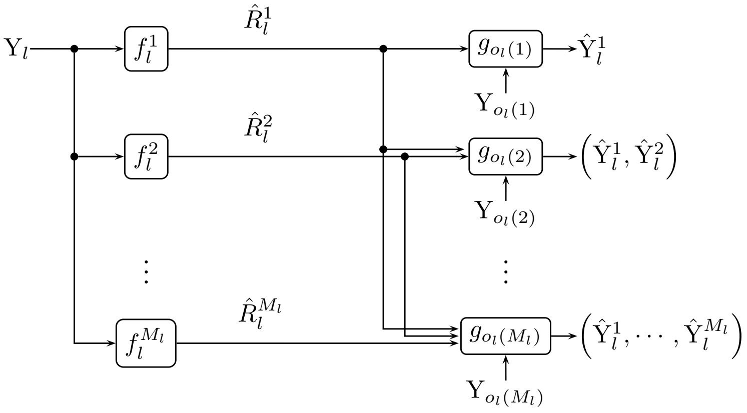

Fig. 3. The successive refinement problem as it emerges in our protocol. Y_l needs to be quantized by encoders $f_l^1, \cdots, f_l^{M_l}$ at different distortions and to be decoded by decoders $g_{o_l(1)}, \cdots, g_{o_l(M_l)}$, $M_l = N-l+1$, which can exploit their own channel output as side information.

$\left(z_l^1, z_l^2\right)$
$y_{l,M}$
$g_{l,M}$
$\left(z_l^1, z_l^2, \cdots, z_l^M\right)$

Fig. 4. The broadcast channel problem considered in our work. The indices $z_l^{[1;k]}$ are determined by the Wyner-Ziv coding of the quantizations $\hat{\text{Y}}_l^{[1;k]}$ and need to be decoded by receiver $g_{l,k}, \cdots, g_{l,M_l}$, $M_l = N-l+1$.

given by the Wyner-Ziv source coding rate [14], i. e., $\hat{R}_l^1 = \max_{i\in[1;M_l]} R^{\text{WZ}}_{\text{Y}_l|\text{Y}_{o_l(i)}}(D_l^1)$, where $R^{\text{WZ}}_{\cdot|\cdot}(\cdot)$ is the Wyner-Ziv rate-distortion function as defined in [5]. In the next refinement step all levels $o_l(i)$, $i \geq 2$, additionally decode the more accurate description $\hat{\text{Y}}_l^2$ with $D_l^2 < D_l^1$. To describe the refined quantization $\hat{\text{Y}}_l^2$ additional information at rate $\hat{R}_l^2$ must be provided. Again from rate-distortion theory we know that $\hat{R}_l^2 + \hat{R}_l^1 \geq \max_{i\in[2;M_l]} R^{\text{WZ}}_{\text{Y}_l|\text{Y}_{l,i}}(D_l^2)$. In [12], [13] the Markovity condition to achieve rate-distortion optimal successive refinements is derived. In our setting this implies the Markov chain $\text{Y}_l \leftrightarrow \hat{\text{Y}}_l^{M_l} \leftrightarrow \hat{\text{Y}}_l^{M_l-1} \leftrightarrow \cdots \hat{\text{Y}}_l^1$. With this condition we can ensure that $\hat{\text{Y}}_l^{k'}$ is at least for one node $o_l(i)$, $i \geq k'$, rate-distortion optimal, i. e., $\sum_{i=1}^{k'} \hat{R}_l^i = \max_{i\in[k';M_l]} R^{\text{WZ}}_{\text{Y}_l|\text{Y}_{l,i}}(D_l^{k'})$.

*d) **The broadcast channel problem**:* Fig. 4 illustrates the problem of transmitting the quantizations of level l, i. e., $\hat{\text{Y}}_l^{[1;M_l]}$, to the next M_l levels: the message indices $(z_l^1, \ldots, z_l^{M_l})$, $z_l^{k'} \in [1; 2^{n\hat{R}_l^{k'}}]$, are determined by the quantizations $\hat{\text{Y}}_l^1, \ldots, \hat{\text{Y}}_l^{M_l}$ using a random binning procedure [4]. As previously mentioned, nodes $o_l(i)$, $i \in [k'; M_l]$, need the indices $(z_l^1, \ldots, z_l^{k'})$ to successfully decode the quantizations $\hat{\text{Y}}_l^1, \ldots, \hat{\text{Y}}_l^{k'}$. Our problem is characterized by a broadcast channel with the degraded message set $\text{W}_l^{[1;M_l]}$, which was analyzed by Körner and Marton [15]. Using the results of [15] we can state that

$$\hat{R}_l^k \le \min_{i\in[k;M_l]} \mathrm{I}\left(\mathrm{W}_l^k;\mathrm{Y}_{l,i}|\mathrm{W}_l^{[1;k-1]}\right) \tag{2}$$

is an achievable rate for our problem. As explained in [16, Corollary 5], (2) is included in the capacity region for the case of $M_l = 2$: $\hat{R}_l^1 \le \mathrm{I}(\mathrm{W}_l^1;\mathrm{Y}_{l,1})$, $\hat{R}_l^2 \le \mathrm{I}(\mathrm{W}_l^2;\mathrm{Y}_{l,2}|\mathrm{W}_l^1)$ and $\hat{R}_l^1 + \hat{R}_l^2 \le \mathrm{I}(\mathrm{W}_l^2;\mathrm{Y}_{l,2})$ [15]. In the special case that $\mathrm{Y}_{o_l(2)}$ is not "less noisy" than $\mathrm{Y}_{o_l(1)}$ [15], i. e., $\mathrm{I}(\mathrm{W}_l^1;\mathrm{Y}_{l,1}) > \mathrm{I}(\mathrm{W}_l^1;\mathrm{Y}_{l,2})$, we need to introduce a time-sharing and auxiliary random variable to achieve capacity [17]. Since the generalization of this method to prove the capacity region of our setting is beyond the scope of this paper we use (2) in the sequel.

Based on the previous description we can formulate the achievable rates for the mixed strategy in Theorem 1.

Theorem 1: With the previously presented protocol we are able to achieve any rate

$$R = \sup_p \max_{o_s\in\pi([1;N+1])} \sum_{k=1}^{N+1} R_s^k \tag{3}$$

iff

$$\begin{aligned} R_s^k < \min_{l\in[k;N+1]} &\mathrm{I}\left(\mathrm{U}_s^k;\mathrm{Y}_l,\hat{\mathrm{Y}}_{l'\in[1;k-1]}^{\phi_{l'}(l)}|\mathrm{U}_s^{[1;k-1]},\left\{\mathrm{V}_{[i;N]}^i,\mathrm{W}_i^{[1;\phi_i(l)]}:i\in[1;l]\right\}\right) + \\ &\sum_{j=k}^{l-1}\mathrm{I}\left(\mathrm{V}_j^k;\mathrm{Y}_l|\mathrm{V}_j^{[1;k-1]},\left\{\mathrm{V}_i^{[1;i]},\mathrm{W}_i^{[1;\phi_i(l)]}:i\in[j+1;l]\right\},\mathrm{V}_{[l;N]}^{[1;l]}\right), \end{aligned} \tag{4}$$

and n and B are sufficiently large. We further have to constrain the broadcast messages:

$$\begin{aligned} \hat{R}_l^j < \min_{\substack{k\in[j;M_l]\\ k'=o_l(k)}} &\mathrm{I}\left(\mathrm{W}_l^j;\mathrm{Y}_{k'}|\mathrm{V}_l^{[1;l]},\mathrm{W}_l^{[1;j-1]},\left\{\mathrm{V}_i^{[1;i]},\mathrm{W}_i^{[1;\phi_i(k')]}:i\in[l+1;k']\right\},\mathrm{V}_{[k'+1;N]}^{[1;k']}\right), \\ &l\in[1;N+1], j\in[1;M_l]. \end{aligned} \tag{5}$$

Finally, we have the following source coding constraints on the quantizations:

$$\begin{aligned} \sum_{i=1}^m \hat{R}_l^i > \max_{\substack{j\in[m;M_l]\\ j'=o_l(j)}} &\mathrm{I}\Big(\hat{\mathrm{Y}}_l^m;\mathrm{Y}_l|\mathrm{Y}_{j'},\hat{\mathrm{Y}}_{i\in[1;l-1]}^{\phi_i(j')},\mathrm{U}_s^{[1;l]},\left\{\mathrm{V}_{[i;N]}^i,\mathrm{W}_i^{[1;\phi_i(j')]}:i\in[1;j']\right\}\Big), \\ &l\in[1;N], m\in[1;M_l]. \end{aligned} \tag{6}$$

Eq. (5) and (6) show the source-channel separation in our proposal which is suboptimal in general. The supremum in (3) is over all pdf of the following form

$$\begin{aligned} &p\left(\mathrm{u}_s^{[1;N+1]},\mathrm{v}_{i\in[1;N]}^{[1;i]},\mathrm{w}_{i\in[1;N]}^{[1;M_i]},\hat{\mathrm{y}}_{i\in[1;N]}^{[1;M_i]},\mathrm{y}_{[1;N+1]}\right) = \\ &p\left(y_{[1;N+1]}|\mathrm{u}_s^{[1;N+1]},\mathrm{w}_{i\in[1;N]}^{[1;M_i]},\mathrm{v}_{i\in[1;N]}^{[1;i]}\right)\cdot\prod_{k=1}^{N+1}p\left(\mathrm{u}_s^k|\mathrm{u}_s^{[1;k-1]},\mathrm{v}_{i\in[k;N]}^k\right)\cdot \\ &\prod_{l=1}^{N}\left[\prod_{k=1}^{l}p\left(\mathrm{v}_l^k|\mathrm{v}_l^{[1;k-1]},\mathrm{v}_{[l+1;N]}^k\right)\cdot p\left(\hat{\mathrm{y}}_l^{M_l}|\mathrm{y}_l,\mathrm{u}_s^{[1;l]},\mathrm{v}_{m\in[1;l]}^{[1;m]},\mathrm{v}_{[l+1;N]}^{[1;l]},\mathrm{w}_{[1;l]}^1\right)p\left(\mathrm{w}_l^{M_l}|\mathrm{w}_l^{[1;M_l-1]},\mathrm{v}_l^{[1;l]}\right)\cdot\right. \\ &\left.\prod_{k=1}^{M_l-1}\left(p\left(\mathrm{w}_l^k|\mathrm{w}_l^{[1;k-1]},\mathrm{v}_l^{[1;l]}\right)p\left(\hat{\mathrm{y}}_l^k|\mathrm{u}_s^{[1;l]},\hat{\mathrm{y}}_l^{k+1},\mathrm{v}_{m\in[1;l]}^{[1;m]},\mathrm{v}_{[l+1;N]}^{[1;l]},\mathrm{w}_{[1;l]}^1\right)\right)\right]. \end{aligned} \tag{7}$$

Proof: See Appendix I. ■

IV. RESULTS FOR THE GAUSSIAN CHANNEL

In the following we apply the previously described mixed strategy to Gaussian multiple relay channels and evaluate performance and complexity of different protocols generalized by it.

A. Description of model

Again, we consider a network of $N+2$ nodes where $d_{l',l}$ denotes the distance between nodes l' and $l \neq l'$. Let θ be the pathloss exponent, then the gain factor between both nodes is given in a log-distance path loss model by $h_{l',l} = d_{l',l}^{-\theta/2}$. Furthermore, let the channel input at node l be given by $\mathrm{X}_l \overset{n}{\sim} \mathcal{CN}\left(0, P_l\right)$, i. e., the channel input is a n-length sequence of i.i.d. Gaussian r.v.s with zero mean and variance $\sigma_{\mathrm{X}}^2 = n^{-1}\sum_{t=1}^{n} \mathrm{E}\left\{\left|\mathrm{X}_l[t]\right|^2\right\}$. Our analysis uses Gaussian alphabets which are not necessarily optimal but easier to treat. The channel output at node l and time t is given by

$$\mathrm{Y}_l[t] = \sum_{l' \in [0;N]\setminus l} h_{l',l}\mathrm{X}_{l'}[t] + Z_l[t],$$

where $Z_l \overset{n}{\sim} \mathcal{CN}\left(0, N_l\right)$ is the additive white Gaussian noise. We further use the following messages

- the partial source messages $\mathrm{U}_s^k \overset{n}{\sim} \mathcal{CN}\left(0,1\right)$, $k \in [1; N+1]$,
- the support messages $\mathrm{V}_l^k \overset{n}{\sim} \mathcal{CN}\left(0,1\right)$, $l \in [1;N], k \in [1;l]$,
- the quantizations $\hat{\mathrm{Y}}_l^{k'} \overset{n}{\sim} \mathcal{CN}\left(0, N_l + \sum_{i=k'}^{M_l} N_l^i\right)$, $k' \in [1; M_l]$ with $M_l = N - l + 1$, where $\sum_{i=k'}^{M_l} N_l^i$ models the quantization noise to compress the channel output Y_l,
- and the broadcast messages $\mathrm{W}_l^{k'} \overset{n}{\sim} \mathcal{CN}\left(0,1\right)$.

The combination of the partial source messages and the support of the relay transmissions is done as follows:

$$\mathrm{X}_s = \sqrt{P_s}\sum_{k=1}^{N+1}\left(\sqrt{\alpha_{s,s}^k}\mathrm{U}_s^k + \sum_{l'=k}^{N}\left(\sqrt{\alpha_{s,l'}^k}\mathrm{V}_{l'}^k\right)\right), \tag{8}$$

where P_s is the source transmission power and $\alpha_{s,l}^k$ is the fraction of power spent by the source node for the support of message level k sent by level l. The channel input at level l is given by

$$\mathrm{X}_l = \sqrt{P_l}\left(\sum_{k=1}^{l}\sum_{l'=l}^{N}\sqrt{\alpha_{l,l'}^k}\mathrm{V}_{l'}^k + \sum_{k=1}^{M_l}\sqrt{\beta_l^k}\mathrm{W}_l^k\right), \tag{9}$$

where β_l^k defines the fraction of power spent by node l for broadcast message level k. Moreover, to meet the power constraints on all channel inputs, we must ensure that

$$\sum_{k=1}^{N+1}\left[\alpha_{s,s}^k + \sum_{l'=k}^{N}\alpha_{s,l'}^k\right] \leq 1, \text{ and } \sum_{k=1}^{l}\sum_{l'=l}^{N}\alpha_{l,l'}^k + \sum_{k=1}^{M_l}\beta_l^k \leq 1. \tag{10}$$

In the case that no coherent transmission is possible it follows that $\alpha_{l,l'}^k = 0$ for $l \neq l'$.

B. Achievable rates

Before we formulate the achievable rates, we need to derive some auxiliary variables. Due to the possibility of coherent transmission, the overall received power at level l' for message level k sent by level l is given by $\Gamma_{l,l'}^k$ and defined by

$$\Gamma_{l,l'}^k = \left(\sum_{j=k}^{l}\left(h_{j,l'}\sqrt{\alpha_{j,l}^k P_j}\right) + h_{s,l'}\sqrt{\alpha_{s,l}^k P_s}\right)^2, \tag{11}$$

$$\Gamma_{s,l'}^k = h_{s,l'}^2\alpha_{s,s}^k P_s, \text{ and } \Gamma_{l\in\mathcal{T},l'}^{[1;l]} = \sum_{l\in\mathcal{T}}\Gamma_{l,l'}^{[1;l]}. \tag{12}$$

Furthermore, the cross-correlation of message level k sent by level l and received at nodes m and m' is denoted as $\tilde{\Gamma}^{k}_{l,m,m'}$ and given by

$$\tilde{\Gamma}^{k}_{l,m,m'} = \left(\sum_{j \in \{[k;l],s\}} h_{j,m} \sqrt{\alpha^{k}_{j,l} P_j} \right) \cdot \left(\sum_{j \in \{[k;l],s\}} h_{j,m'} \sqrt{\alpha^{k}_{j,l} P_j} \right), \tag{13}$$

$$\tilde{\Gamma}^{k}_{s,m,m'} = h_{s,m} h_{s,m'} \alpha^{k}_{s,s} P_s, \text{ and } \tilde{\Gamma}^{[k;k']}_{l \in \mathcal{T},m,m'} = \sum_{l \in \mathcal{T}} \tilde{\Gamma}^{[k;k']}_{l,m,m'}. \tag{14}$$

The power of broadcast messages received at node l after decoding the broadcast messages of levels $[k;k']$ is given by

$$\Lambda^{k,k'}_{l} = \sum_{m \in [1;N] \setminus [k;k']} h^2_{m,l} \beta^{[1;M_m]}_{m} P_m + \sum_{m \in [k;k'-1]} h^2_{m,l} \beta^{[\phi_m(k')+1;M_m]}_{m} P_m. \tag{15}$$

Finally, let us define the matrix $\mathbf{K}^{j,j'}_{s,l}$ as the covariance matrix of Y_l and all decoded quantizations $\hat{\mathrm{Y}}^{\phi_{l'}(l)}_{l' \in [1;j-1]}$ when decoding the partial source message U^{j}_{s} and knowing $\mathrm{U}^{[1;j']}_{s}$. The elements of the matrix are given by

$$\left[\mathbf{K}^{j,j'}_{s,l}\right]_{1,1} = \Gamma^{[l+1;l']}_{l' \in [l+1;N],l} + \Gamma^{[j'+1;N+1]}_{s,l} + \Lambda^{1,l}_{l} + N_l, \tag{16}$$

$$\left[\mathbf{K}^{j,j'}_{s,l}\right]_{1+i,1+i} = \Gamma^{[l+1;l']}_{l' \in [l+1;N],i} + \Gamma^{[j'+1;N+1]}_{s,i} + \Lambda^{1,l}_{i} + N_i + \sum_{i'=\phi_i(l)}^{M_i} N^{i'}_{i}, \tag{17}$$

$$\left[\mathbf{K}^{j,j'}_{s,l}\right]_{1,1+i} = \tilde{\Gamma}^{[l+1;l']}_{l' \in [l+1;N],l,i} + \tilde{\Gamma}^{[j'+1;N+1]}_{s,l,i}, \tag{18}$$

$$\left[\mathbf{K}^{j,j'}_{s,l}\right]_{1+i,1+i'} = \tilde{\Gamma}^{[l+1;l']}_{l' \in [l+1;N],i,i'} + \tilde{\Gamma}^{[j'+1;N+1]}_{s,i,i'}, \tag{19}$$

for $i, i' \in [1, j-1]$ and $i \neq i'$. Using the previously given variables and the specific decoding scheme described above we can formulate Theorem 2 on the achievable rates in a Gaussian multiple relay network.

Theorem 2: With the previously presented protocol we are able to achieve any rate

$$R = \max_{o_s \in \pi([1;N+1])} \sum_{k=1}^{N+1} R^{k}_{s} \tag{20}$$

in the Gaussian multiple relay network iff

$$\begin{aligned} R^{k}_{s} < \min_{l \in [k;N+1]} \log \left(\frac{\det K^{k-1,k-1}_{s,l}}{\det K^{k-1,k}_{s,l}} \right) + \\ \sum_{j=k}^{l-1} \mathrm{C} \left(\frac{\Gamma^{k}_{j,l}}{\Gamma^{[1;l']}_{l' \in [1;j-1],l} + \Gamma^{[k+1;j]}_{j,l} + \Gamma^{[l+1;l']}_{l' \in [l+1;N],l} + \Lambda^{j+1,l}_{l} + \Gamma^{[1;N+1]}_{s,l} + N_l} \right). \end{aligned} \tag{21}$$

and n and B are sufficiently large. We further have to constrain the broadcast messages using the following upper bound

$$\hat{R}^{j}_{l} < \min_{\substack{k \in [j;M_l] \\ k' = o_l(k)}} \mathrm{C} \left(\frac{h^2_{l,k'} \beta^{j}_{l} P_l}{\Gamma^{[1;l']}_{l' \in [1;l-1],k'} + \Gamma^{[k'+1;l']}_{l' \in [k'+1;N],k'} + \Lambda^{l+1,k'}_{k'} - h^2_{l,k'} \sum_{i=1}^{j} \beta^{i}_{l} P_l + \Gamma^{[1;N+1]}_{s,k'} + N_{k'}} \right), \tag{22}$$

$$l \in [1;N+1], j \in [1;M_l],$$

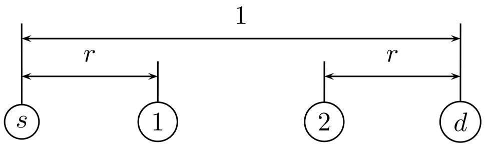

Fig. 5. Setup for our analysis

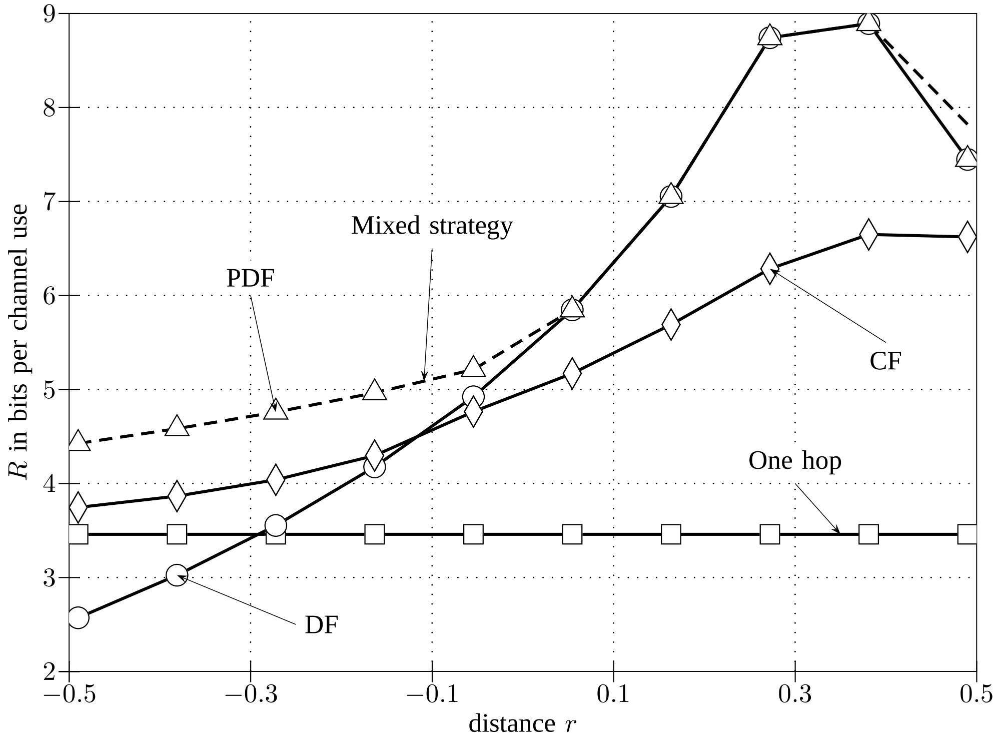

Fig. 6. Achievable rates for *coherent* transmission, $\theta = 4$, $\gamma_{s,d} = 10\,\mathrm{dB}$ and the setup given in Fig. 5

Finally, we have the following source coding constraints on the quantizations:

$$\sum_{i=m}^{M_l} N_l^i > \max_{\substack{j\in[m;M_l]\\ j'=o_l(j)}} \frac{\Gamma_{l'\in[j'+1;N],l}^{[j'+1;l']} + \Gamma_{s,l}^{[l+1;N+1]} + \Lambda_l^{1,j'} + N_l - \frac{\left(\tilde{\Gamma}_{l'\in[j'+1;N],j',l}^{[j'+1;l']} + \tilde{\Gamma}_{s,j',l}^{[l+1;N+1]}\right)^2}{\Gamma_{l'\in[j'+1;N],j'}^{[j'+1;l']} + \Gamma_{s,j'}^{[l+1;N+1]} + \Lambda_{j'}^{1,j'} + N_{j'}}}{2^{\sum_{i=1}^{m} \hat{R}_l^i} - 1}. \tag{23}$$

Proof: See Appendix II. ■

C. Numerical results

In this section we apply the previously presented approach to the setup with $N = 2$ relay nodes illustrated in Fig. 5. In this setup all distances are normalized to the source destination distance, i. e., $d_{s,d} = 1$, $d_{s,1} = d_{2,d} = |r|$ and $d_{1,2} = 1 - 2r$. Furthermore, let $N_1 = N_2 = \cdots N_d$, $P_s = P_1 = \cdots P_N$ and $\gamma_{s,d} = {}^{P_s}/_{N_d} = 10\,\mathrm{dB}$. Other values of $\gamma_{s,d}$ would impact the quantitative statements given in the following but the qualitative statements remain almost unaffected. We compare the results of coherent transmission with noncoherent transmission for a pathloss

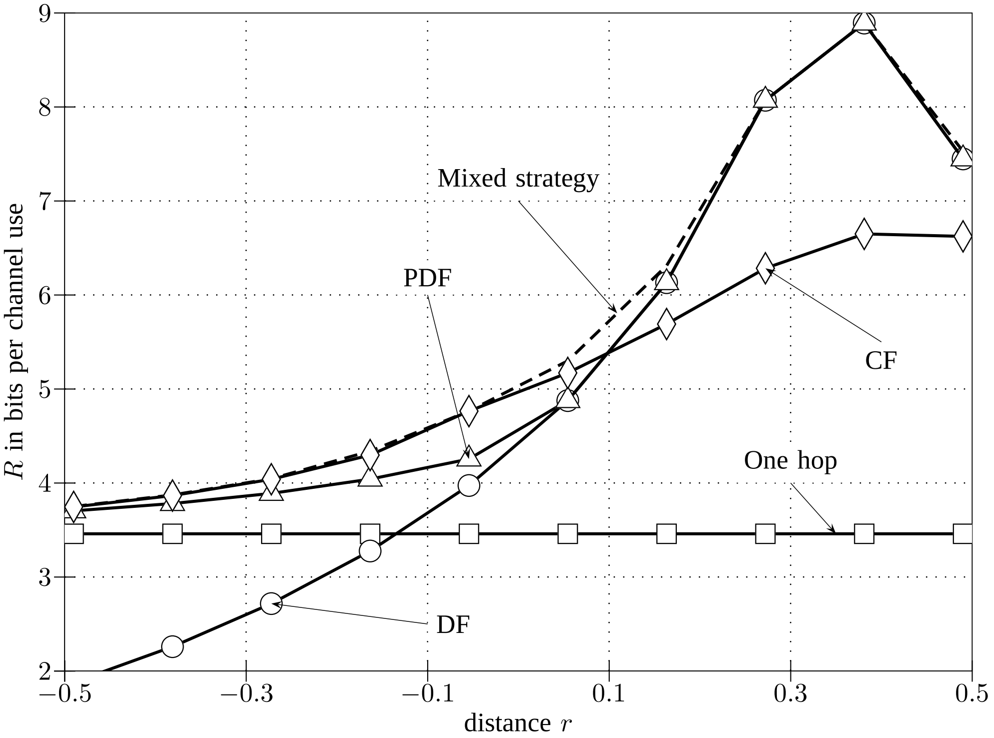

Fig. 7. Achievable rates for *noncoherent* transmission, $\theta = 4$, $\gamma_{s,d} = 10\,\mathrm{dB}$ and the setup given in Fig. 5

exponent $\theta = 4$.

Before we analyze the results for the given setup we need to introduce some special cases of the presented approach which, as we see later, achieve its performance in certain scenarios:

1) **DF**: The pure decode-and-forward case was presented in [7] where only one source message level is used, i. e., only U_s^1 and $\mathrm{V}_{l\in[1;N]}^1$ are used. In this case the encoding and decoding complexity of the mixed strategy is minimized.
2) **CF**: Assume the source node only uses the partial message U_s^{N+1} (by setting $\alpha_{s,s}^{[1;N]} = 0$). In this case each relay node only transmits its quantization to the destination node. Hence, the decoding complexity at the destination is increased in comparison to the DF approach. Note that this protocol is comparable to the ideas of [10, Theorem 3].
3) **PDF**: This protocol relates to a parameterization with $\beta_{l\in[1;N]}^{[1;M_l]} = 0$, i. e., the relay nodes do not quantize their channel output. This partial decode-and-forward approach can be seen as a more general form of DF.
4) **Mixed CF/DF**: The last special case can be applied for the two-relay case when the first relay node operates in CF mode to support the second relay node which operates in (single-level) DF mode. In this way the first relay helps to increase the rate towards the second relay which on the other hand can provide more additional information to the destination.

Consider Fig. 6 which shows the maximum achievable rates for direct transmission (one hop), the presented approach and its special cases (except for the mixed CF/DF case which is discussed later) in the described setup when coherent transmission is possible. It shows that the PDF approach achieves the performance of the presented strategy at all r except for $r \approx 0.5$. This implies that the additional quantization stages provide only minor or no benefits. A less complex protocol is DF which for $0 \leq r \leq 0.5$ also achieves the performance of the described strategy at much less encoding and decoding complexity. A closer look on the actual parameters reveals that the performance difference between PDF and DF for $r < 0$ is due to the fact that in DF all relays must decode the source message whereas in PDF an appropriate parameterization can be chosen such that one relay node is not used anymore. Hence, for $r < 0$ the single hop DF and for $0 \leq r \leq 0.5$ the multihop DF achieve the best performance while requiring the least encoding and decoding complexity. We can further observe in both figures that the CF strategy does not achieve the other protocols' performance in the observed interval $-0.5 \leq r \leq 0.5$. This coincides with the results for one relay where CF can only achieve the general lower bound if the relay is placed closer to the destination (as in this region the broadcast cut is the limiting factor). In contrast to the one relay setup, we have in our setup always one relay node with a sufficiently good link to the source node such that CF would only achieve the rate of the mixed strategy for $r \leq -0.5$.

Now consider Fig. 7 which shows the results when no coherent transmission is possible. In this case, the behavior of the presented protocols slightly changes, e. g., CF is now able to achieve the performance of the mixed strategy for $r \leq$ and both PDF and DF only provide the best performance for $0.2 \leq r$. This again coincides with the results for the one-relay case where coherent transmission only provides benefits for $r \leq 0.5$. Nonetheless, in the more interesting case (from a practical point of view) where the relays are place between source and destination, the DF approach again offers the best performance (and performs as good as PDF) which again shows that the DF approach offers the best complexity-benefit tradeoff in a wide range of scenarios.

In both figures $r = 0.5$ represents a special point as none of the illustrated protocols achieves the performance of our approach. Consider again the mixed CF/DF strategy where the first relay node supports the second relay node by communicating its quantized channel output and the second relay node uses these quantizations to operate in single DF mode. At $r = 0.5$ this protocol achieves the best performance (the protocol is not shown as it does not provide any advantage at other values of r).

APPENDIX I

PROOF OF THEOREM 1

This section proves Theorem 1 using the arguments developed in [9] as well as strongly ϵ-typical sequences as defined in [11, Ch. 13.6]. The necessity for strongly ϵ-typical sequences arises from the usage of quantizations which requires the Markov lemma [11, Lemma 14.8.1]. Before we can describe the proof in more detail we need to derive the following lemma which is a basic part of this proof.

Lemma 1: Let the n-length tupel (x, y, u, w) be drawn from $(\mathrm{X}, \mathrm{Y}, \mathrm{U}, \mathrm{W}) \overset{n}{\sim} p(\mathrm{x}|\mathrm{u})p(\mathrm{y}|\mathrm{u}, \mathrm{w})p(\mathrm{w}, \mathrm{u})$, then

$$P_e = \Pr\left\{(\mathrm{x}, \mathrm{y}, \mathrm{u}, \mathrm{w}) \in \mathcal{A}_\epsilon^{*(n)}\right\} \doteq 2^{-nI(\mathrm{X};\mathrm{YW}|\mathrm{U})}, \tag{24}$$

where $\doteq$ is used as defined in [11].

Proof:

$$P_e = \sum_{(\mathrm{x},\mathrm{y},\mathrm{u},\mathrm{w}) \in \mathcal{A}_\epsilon^{(n)}} p(\mathrm{x}|\mathrm{u})p(\mathrm{y}|\mathrm{u}, \mathrm{w})p(\mathrm{w}, \mathrm{u}) \tag{25}$$

$$= \left\|\mathcal{A}_\epsilon^{(n)}\right\| 2^{-n(H(\mathrm{X}|\mathrm{U})-2\epsilon)} 2^{-n(H(\mathrm{Y}|\mathrm{WU})-2\epsilon)} 2^{-n(H(\mathrm{WU}-\epsilon)} \tag{26}$$

$$= 2^{n(H(\mathrm{XYWU})+\epsilon)} 2^{-n(H(\mathrm{X}|\mathrm{U})-2\epsilon)} 2^{-n(H(\mathrm{Y}|\mathrm{WU})-2\epsilon)} 2^{-n(H(\mathrm{WU})-\epsilon)} \tag{27}$$

$$= 2^{-n(K-6\epsilon)} \tag{28}$$

where K is given by

$$K = -H(\mathrm{XYWU}) + H(\mathrm{X}|\mathrm{U}) + H(\mathrm{Y}|\mathrm{WU}) + H(\mathrm{WU}) \tag{29}$$

$$= \mathrm{I}(\mathrm{X};\mathrm{W}|\mathrm{U}) + \mathrm{I}(\mathrm{X};\mathrm{Y}|\mathrm{WU}) \tag{30}$$

$$\overset{(a)}{=} \mathrm{I}(\mathrm{X};\mathrm{YW}|\mathrm{U}) \tag{31}$$

and (a) follows from the chain rule. ■

Corollary 1: Note that if the Markov condition $\mathrm{X} \leftrightarrow \mathrm{U} \leftrightarrow \mathrm{W}$ holds then

$$\mathrm{I}\left(\mathrm{X};\mathrm{Y},\mathrm{W}|\mathrm{U}\right) = \mathrm{I}\left(\mathrm{X};\mathrm{Y}|\mathrm{W},\mathrm{U}\right), \tag{32}$$

as an immediate consequence of the chain rule for mutual information.

A. Random coding

We consider in the following $N+1$ codebooks $C_i, i \in [0;N]$, where in block b codebook $C_{\mathrm{mod}(b,N+1)}$ is used. The sequences for each codebook are generated as described in the following.

- **Relay level N** creates the sequences $\mathrm{v}_N^k\left(q_N^k|q_N^{[1;k-1]}\right), k \in [1;N], q_N^k \in [1;2^{nR_s^k}]$, which are drawn from $\mathrm{V}_N^k \overset{n}{\sim} p\left(\mathrm{v}_N^k|\mathbf{v}_N^{i\in[1;k-1]}\left(q_N^i|q_N^{[1;i-1]}\right)\right)$ for each $q_N^{[1;k-1]}$. Then it creates the broadcast messages $\mathrm{w}_N^1\left(z_N^1|q_N^{[1;N]}\right)$, $z_N^1 \in [1;2^{n\hat{R}_N^1}]$, drawn from

$$\mathrm{W}_N^1 \overset{n}{\sim} p\left(w_N^1|\mathbf{v}_N^{i\in[1;N]}\left(q_N^i|q_N^{[1;i-1]}\right)\right), \tag{33}$$

  where $\mathbf{v}_N^{i\in[1;k-1]}\left(q_N^i|q_N^{[1;i-1]}\right)$ abbreviates the set $\left\{\mathrm{v}_N^i\left(q_N^i|q_N^{[1;i-1]}\right) : i \in [1;k-1]\right\}$. The sequences are always generated in an ascending order, i. e., starting with all $q_N^1 \in [1;2^{nR_s^1}]$ and proceeding with increasing k. Furthermore, the quantization messages $\hat{\mathrm{y}}_N^1\left(r_N^1\middle|\ q_s^{[1;N]}, \left\{q_{[i;N]}^i, z_i^1 : i \in [1;N]\right\}\right)$, $r_N^1 \in \left[1;2^{n\Delta_N^1}\right]$, are drawn from

$$\begin{aligned}\hat{\mathrm{Y}}_N^1 \overset{n}{\sim} p\Big(&\hat{\mathrm{y}}_N^1|\mathbf{u}_s^{m\in[1;N]}\left(q_s^m|q_s^{[1;m-1]}, \left\{q_{[i;N]}^i : i \in [1;m]\right\}\right),\\ &\left\{\mathbf{v}_m^{i\in[1;m]}\left(q_m^i|q_m^{[1;i-1]}, q_{[m+1;N]}^{[1;i]}\right), \mathrm{w}_m^1\left(z_m^1|q_{[m;N]}^{[1;m]}\right) : m \in [1;N]\right\}\Big),\end{aligned} \tag{34}$$

  for each $q_s^{[1;N]}, \left\{q_{[i;N]}^i, z_i^1 : i \in [1;N]\right\}$. We further use the following *random partitioning*: Each $r_N^1 \in [1;2^{n\Delta_N^1}]$ is randomly assigned to one of the cells $Z_N^1(z_N^1)$, $z_N^1 \in [1;2^{n\hat{R}_N^1}]$, according to a uniform distribution.
- **Relay level *l***, $l \in [1;N]$, creates the supporting messages $\mathrm{v}_l^k\left(q_l^k|q_l^{[1;k-1]}, q_{[l+1;N]}^{[1;k]}\right)$, $k \in [1;l], q_l^k \in \left[1;2^{nR_s^k}\right]$, drawn from

$$\mathrm{V}_l^k \overset{n}{\sim} p\left(\mathrm{v}_l^k|\mathbf{v}_l^{i\in[1;k-1]}\left(q_l^i|q_l^{[1;i-1]}, q_{[l+1;N]}^{[1;i]}\right), \mathbf{v}_{i\in[l+1;N]}^k\left(q_i^k|q_i^{[1;k-1]}, q_{[i+1;N]}^{[1;k]}\right)\right), \tag{35}$$

  for each $q_l^{[1;k-1]}, q_{[l+1;N]}^{[1;k]}$. In the next step we create the broadcast sequences $\mathrm{w}_l^k\left(z_l^k|z_l^{[1;k-1]}, q_{[l;N]}^{[1;l]}\right)$, $k \in [1;M_l]$, $z_l^k \in \left[1;2^{n\hat{R}_l^k}\right]$, which are drawn from

$$\mathrm{W}_l^k \overset{n}{\sim} p\left(\mathrm{w}_l^k|\mathbf{w}_l^{i\in[1;k-1]}\left(z_l^i|z_l^{[1;i-1]}, q_{[l;N]}^{[1;l]}\right)\mathbf{v}_l^{i\in[1;l]}\left(q_l^i|q_l^{[1;i-1]}, q_{[l+1;N]}^{[1;i]}\right)\right), \tag{36}$$

for each $z_l^{[1;k-1]}, q_{[l;N]}^{[1;l]}$. We further create the quantizations $\hat{\mathrm{y}}_l^k \left(r_l^k \middle| \, r_l^{[1;k-1]}, q_s^{[1;l]}, \left\{q_{[i;N]}^i, z_i^1 : i \in [1;l]\right\}\right)$, $k \in [1;M_l], r_l^k \in \left[1; 2^{n\left(\Delta_l^k - \Delta_l^{k-1}\right)}\right]$, which are drawn from

$$\begin{aligned}\hat{\mathrm{Y}}_l^k \overset{n}{\sim} p\Big(&\hat{\mathrm{y}}_l^k | \mathbf{u}_s^{m\in[1;l]} \left(q_s^m | q_s^{[1;m-1]}, \left\{q_{[i;N]}^i : i \in [1;m]\right\}\right), \\ &\hat{\mathrm{y}}_l^{k-1} \left(r_l^{k-1} | r_l^{[1;k-2]}, q_s^{[1;l]}, \left\{q_{[i;N]}^i, z_i^1 : i \in [1;l]\right\}\right), \\ &\left\{\mathbf{v}_m^{i\in[1;m]} \left(q_m^i | q_m^{[1;i-1]}, q_{[m+1;N]}^{[1;i]}\right), \mathrm{w}_m^1 \left(z_m^1 | q_{[m;N]}^{[1;m]}\right) : m \in [1;l]\right\}, \\ &\left\{\mathbf{v}_m^{i\in[1;l]} \left(q_m^i | q_m^{[1;i-1]}, q_{[m+1;N]}^{[1;i]}\right) : m \in [l+1;N]\right\}\Big),\end{aligned} \tag{37}$$

for each $r_l^{[1;k-1]}, q_s^{[1;l]}, \left\{q_{[i;N]}^i, z_i^1 : i \in [1;l]\right\}$. The joint pdf in (7) as well as the generation of quantization messages shows the Markov chain $\hat{\mathrm{Y}}_l^{M_l} \leftrightarrow \hat{\mathrm{Y}}_l^{M_l-1} \leftrightarrow \cdots \hat{\mathrm{Y}}_l^1$ which is used in the sequel in the context of the successive refinement problem. We further use the following *random partitioning*: Each $r_l^i \in [1; 2^{n(\Delta_l^i - \Delta_l^{i-1})}]$ is randomly assigned to one of the cells $Z_l^i(z_l^i)$, $z_l^i \in [1; 2^{n\hat{R}_l^i}]$, according to a uniform distribution.

- **The source** generates the sequences $u_s^k \left(q_s^k | q_s^{[1;k-1]}, \left\{q_{[i;N]}^i : i \in [1;k]\right\}\right)$ with $q_s^k \in [1; 2^{nR_s^k}]$, $k \in [1; N+1]$, drawn from

$$\mathrm{U}_s^k \overset{n}{\sim} p\Big(\mathrm{u}_s^k | \mathbf{u}_s^{m\in[1;k-1]} \left(q_s^m | q_s^{[1;m-1]}, \left\{q_{[i;N]}^i : i \in [1;m]\right\}\right), \mathbf{v}_{i\in[k;N]}^k \left(q_i^k | q_i^{[1;k-1]}, q_{[i+1;N]}^{[1;k]}\right)\Big) \tag{38}$$

  for each $q_s^{[1;k-1]}$ and $\left\{q_{[i;N]}^i : i \in [1;k]\right\}$.

Note that all codebooks are revealed to all nodes in the network.

B. Encoding

Note that $q_{s,[B-N+1;B]}^{[1;N+1]} = 0$, $q_{l,[1;l]}^{[1;l]} = 0$ and $q_{l,[B-N+l+1;B]}^{[1;l]} = 0$ which is known to all nodes. Consider now the encoding for block b:

- **At the source node**

  In block b the source transmits the message indices $\left(q_{s,b}^1, \cdots, q_{s,b}^{N+1}\right)$. Assume all relays correctly decoded the previous N source transmissions, then the source knows the indices $q_{k\in[1;N],b}^{[1;k]} = q_{s,b-k}^{[1;k]}$ (and henceforth also the corresponding messages). Therefore, the source transmits the messages

$$\left\{\mathrm{u}_s^l \left(q_{s,b}^l | q_{s,b}^{[1;l-1]}, \left\{q_{[k;N],b}^k : k \in [1;l]\right\}\right) : l \in [1;N]\right\} \tag{39}$$

  from codebook $C_{\mathrm{mod}(b,N+1)}$.

- **At relay level *l***

  Assume the relay successfully decoded $\left\{q_{s,b-l'}^{[1;l]} : l' \in [l;N]\right\}$. In block b level l is supposed to transmit the indices $q_{l,b}^{[1;l]} = q_{s,b-l}^{[1;l]}$. It further knows the indices transmitted by the subsequent relays $q_{l'\in[l+1;N],b}^{[1;l]}$ for the first l source message levels and can therefore support the transmission of these relays.

  Furthermore, let the relay found the quantization indices $\left(r_{l,b-1}^1, \cdots, r_{l,b-1}^{M_l}\right)$ (we define in the decoding section how these indices are found). With $r_{l,b-1}^i \in Z_l^i(z_{l,b}^i), i \in [1;M_l]$, the node can create the messages $\mathrm{w}_l^i(z_{l,b}^i | z_{l,b}^{[1;i-1]}, q_{[l;N],b}^{[1;l]}), i \in [1;M_l]$. The relay finally transmits $\mathrm{v}_l^{k\in[1;l]} \left(q_{l,b}^k | q_{l,b}^{[1;k-1]}, q_{[l+1;N],b}^{[1;k]}\right)$ and $\mathrm{w}_l^{k\in[1;M_l]} \left(z_{l,b}^k | z_{l,b}^{[1;k-1]}, q_{[l;N],b}^{[1;l]}\right)$.

C. Decoding

The decoding is described for some arbitrary node $l \in [1; N+1]$, source message level k and block b.

- At first we decode the quantizations communicated by level $k-1$ (for $k > 1$), i. e., the broadcast message indices $z_{k-1,b-l+k}^{[1;\phi_{k-1}(l)]}$ and the corresponding quantization indices $r_{k-1,b-l+k-1}^{[1;\phi_{k-1}(l)]}$. At first we decode the broadcast message indices $z_{k-1,b-l+k}^{[1;\phi_{k-1}(l)]}$. Then, for each $j \in [1; \phi_{k-1}(l)]$, we build the set

$$\begin{aligned}\mathcal{Q}_{l,k-1,b}^{j} =& \Bigg\{ \tilde{r}_{k-1,b-l+k-1}^{j} : \Big(\mathrm{y}_l(b-l+1), \\ & \hat{\mathrm{y}}_{k-1}^{j} \left(\tilde{r}_{k-1,b-l+k-1}^{j} | r_{k-1,b-l+k-1}^{[1;j-1]}, q_{s,b-l+1}^{[1;k-1]}, \left\{ q_{[i,N],b-l+1}^{i}, z_i^1 : i \in [1;k-1] \right\} \right), \\ & \hat{\mathrm{y}}_{k-1}^{j-1} \left(r_{k-1,b-l+k-1}^{j-1} | r_{k-1,b-l+k-1}^{[1;j-2]}, q_{s,b-l+1}^{[1;k-1]}, \left\{ q_{[i,N],b-l+1}^{i}, z_{i,b-l+1}^1 : i \in [1;k-1] \right\} \right), \\ & \hat{\mathbf{y}}_{i\in[1;k-2]}^{\phi_i(l)} \left(r_{i,b-l+i}^{\phi_i(l)} | r_{i,b-l+i}^{[1;\phi_i(l)-1]}, q_{s,b-l+1}^{[1;i]}, \left\{ q_{[m,N],b-l+1}^{m}, z_{m,b-l+1}^1 : m \in [1;i] \right\} \right), \\ & \mathbf{u}_s^{[1;k-1]}, \left\{ \mathbf{v}_i^{m\in[1;i]}, \mathbf{w}_i^{m\in[1;\phi_i(l)]} : i \in [1;l] \right\}, \mathbf{v}_{i\in[l+1;N]}^{[1;l]} \Big) \in \mathcal{A}_\epsilon^{*(n)} \Bigg\},\end{aligned} \tag{40}$$

  where we dropped the block index $b-l+1$ if it is clear from the context. The set $\mathcal{Q}_{l,k-1,b}^{j}$ holds all possible quantization indices $\tilde{r}_{k-1,b-l+k-1}^{j}$ and we search for such an unique index which maps to $Z_{k-1}^{j}(z_{k-1,b-l+k}^{j})$ as follows

$$\exists \tilde{r}_{k-1,b-l+k-1}^{j} : \tilde{r}_{k-1,b-l+k-1}^{j} = \mathcal{Q}_{l,k-1,b}^{j} \cap \mathcal{Z}_{k-1}^{j}(z_{k-1,b-l+k}^{j}). \tag{41}$$

  Remark 3: We must note that when decoding source message level k we can only decode the indices of nodes $[k;l]$. Furthermore, we decode in this step only the quantizations of node level $k-1$ which exploits the quantization information acquired in the previous $k-2$ decoding steps (in the first step we do not decode any quantization information).

- Using these quantization messages we proceed with the decoding of the source message $q_{s,b-l+1}^{k}$. Consider at first the following sets:

$$\begin{aligned}\mathcal{T}_{l,b,j}^{k} =& \Bigg\{ \tilde{q}_{j,b-l+1+j}^{k} : \Bigg(\mathrm{v}_j^k \left(\tilde{q}_{j,b-l+1+j}^{k} | q_{j,b-l+1+j}^{[1;k-1]}, q_{[j+1;N],b-l+1+j}^{[1;k]} \right), \mathrm{y}_l(b-l+1+j) \\ & \mathrm{v}_j^{[1;k-1]}, \left\{ \mathrm{v}_i^{[1;i]}, \mathrm{w}_i^{[1;\phi_i(l)]} : i \in [j+1;l] \right\}, \mathrm{v}_{[l;N]}^{[1;l]} \Bigg) \in \mathcal{A}_\epsilon^{*(n)} \Bigg\}\end{aligned} \tag{42}$$

$$\begin{aligned}\mathcal{T}_{l,b,0}^{k} =& \Bigg\{ \tilde{q}_{s,b-l+1}^{k} : \Bigg(\mathrm{u}_s^k \left(\tilde{q}_{s,b-l+1}^{k} | q_{s,b-l+1}^{[1;k-1]}, \left\{ q_{[i;N],b-l+1}^{i} : i \in [1;k] \right\} \right), \mathrm{y}_l(b-l+1) \\ & \hat{\mathrm{y}}_{l'\in[1;k-1]}^{\phi_{l'}(l)} \left(r_{l',b-l+l'}^{\phi_{l'}(l)} | r_{l',b-l+l'}^{[1;\phi_{l'}(l)-1]}, q_{s,b-l+1}^{[1;l']}, \left\{ q_{[j;N],b-l+1}^{j}, z_{j,b-l+1}^1 : j \in [1;l'] \right\} \right) \\ & \mathrm{u}_s^{[1;k-1]}, \left\{ \mathrm{v}_{[i;N]}^{i}, \mathrm{w}_i^{[1;\phi_i(l)]} : i \in [1;l] \right\} \Bigg) \in \mathcal{A}_\epsilon^{*(n)} \Bigg\}\end{aligned} \tag{43}$$

  for all $j \in [k; l-1]$. Note that we dropped in (42) and (43) the block index $b-l+1+j$ where it is uniquely defined by the context. We finally decode $q_{s,b-l+1}^{k}$ iff

$$\exists \tilde{q}_{s,b-l+1}^{k} : \tilde{q}_{s,b-l+1}^{k} = \mathcal{T}_{l,b,0}^{k} \cap \bigcap_{j=k}^{l-1} \mathcal{T}_{l,b,j}^{k}. \tag{44}$$

- Finally, if $l < N+1$, the relay needs to quantize its channel output in block $b-l+1$ after decoding all source message indices $q_{s,b-l+1}^{[1;l]}$. This is done for a suitable quantization index $\tilde{r}_{l,b}^{j}$, $j \in [1; M_l]$, such that

$$\begin{aligned} \exists \tilde{r}_{l,b}^{j} : \Bigg(& \hat{\mathrm{y}}_l^{j}\left(\tilde{r}_{l,b}^{j} | r_{l,b}^{[1;j-1]}, q_{s,b-l+1}^{[1;l]}, \left\{ s_{[i;N],b-l+1}^{i}, z_{i,b-l+1}^{1} : i \in [1;l] \right\}\right), \\ & \hat{\mathrm{y}}_l^{j-1}\left(r_{l,b}^{j-1} | r_{l,b}^{[1;j-2]}, q_{s,b-l+1}^{[1;l]}, \left\{ s_{[i;N],b-l+1}^{i}, z_{i,b-l+1}^{1} : i \in [1;l] \right\}\right), \mathrm{y}_l(b-l+1), \\ & \mathbf{u}_s^{j\in[1;l]}, \left\{ \mathbf{v}_i^{j\in[1;i]}, \mathbf{w}_i^{j\in[1;\phi_i(l)]} : i \in [1;l] \right\}, \mathbf{v}_{i\in[l;N]}^{[1;l]} \Bigg) \in \mathcal{A}_\epsilon^{*(n)}, \end{aligned} \tag{45}$$

  where we again dropped the block index $b-l+1$ if it is uniquely defined by the context.

D. *Definition of error events*

Consider the following error events which might occur using the previous decoding rule:

- $E_{0,b}$: the error that all previously described r.v.s are not ϵ-jointly typical in block b,
- $E_{l,b}^{k}$: the error that level l does not correctly decode in block b source message level $k \in [1;l]$,
- $E_{l,l',b}^{k'}$: the error that level l does not correctly decode in block b the broadcast message $k' \in [1;\phi_{l'}(l)]$ sent by level l',
- $\hat{E}_{l,l',b}^{k'}$: the error that level l does not correctly decode in block b the quantization message $k' \in [1;\phi_{l'}(l)]$ sent by level l', and
- $\hat{E}_{l,b}^{k'}$: the error that level l does not find a quantization index k' in block b.

Now let

$$F_b = E_{0,b} \cup \bigcup_{l=1}^{N+1} \left(\bigcup_{k=1}^{l-1} E_{l,b}^{k} \cup \bigcup_{l'=1}^{l-1} \bigcup_{k'=1}^{\phi_{l'}(l)} \left(E_{l,l',b}^{k'} \cup \hat{E}_{l,l',b}^{k'} \right) \cup \bigcup_{k'=1}^{M_l} \hat{E}_{l,b}^{k'} \right) \tag{46}$$

where $\Pr\left\{E_{N+1,b}^{k'}\right\} = 0$. We can use $\Pr\left\{F_b | F_{b-1}^c \cup F_{b-2}^c \cup \ldots F_{b-N}^c\right\}$ to upper bound the probability of error in block b. Besides, note that $\Pr\left\{F_b | F_{b-1}^c \cup F_{b-2}^c \cup \ldots F_{b-N}^c\right\} = \Pr\left\{F_b | F_{b-1}^c \cup F_{b-1}^c \cup \ldots F_{1}^c\right\}$ as the error in block b only depends on the previous N blocks.

E. *Individual error events probabilities*

Before proving that the overall probability of error is arbitrarily small, we derive now the individual probabilities of the previously listed error events.

1) Event $E_{0,b}$: This event is defined by

$$\Pr\left\{E_{0,b} | F_{[1;b-1]}^c\right\} = \Pr\left\{ \left(\mathrm{u}_s^{[1;N+1]}, \mathrm{v}_{i\in[1;N]}^{[1;i]}, \mathrm{w}_{i\in[1;N]}^{[1;M_i]}, \hat{\mathrm{y}}_{i\in[1;N]}^{[1;M_i]}, \mathrm{y}_{[1;N+1]} \right) \notin \mathcal{A}_\epsilon^{*(n)} \right\}, \tag{47}$$

where we dropped the block index b to improve the readability. From Wyner-Ziv coding [5] as well as compress-and-forward [3, Theorem 6] we know that the proof for this events requires the application of the Markov lemma [11, Lemma 14.8.1] to ensure joint typicality. From the joint pdf in (7) we can define the following Markov chain

$$\begin{aligned} & \hat{\mathrm{Y}}_l^{k} \leftrightarrow \left(\hat{\mathrm{Y}}_l^{k+1}, \mathrm{U}_s^{[1;l]}, \mathrm{V}_{m\in[1;l]}^{[1;m]}, \mathrm{V}_{[l+1;N]}^{[1;l]}, \mathrm{W}_{[1;l]}^{1} \right) \leftrightarrow \\ & \left(\hat{\mathrm{Y}}_l^{[k+2;M_l]}, \mathrm{Y}_{[1;N+1]}, \mathrm{U}_s^{[l+1;N+1]}, \mathrm{V}_{l'\in[l+1;N]}^{[l+1;l']}, \mathrm{W}_{[1;l]}^{[2;M_l]}, \mathrm{W}_{[l+1;N]}^{[1;M_l]} \right) \end{aligned} \tag{48}$$

where $\hat{\mathrm{Y}}_l^{k+1}$ is substituted by Y_l if $k = M_l$. After recursive application of this Markov chain starting with $k = M_l$ we know using the Markov lemma that

$$\Pr\left\{E_{0,b}|F^c_{[1;b-1]}\right\} \leq \epsilon, \tag{49}$$

where $\epsilon \to 0$ as $n \to \infty$.

2) Event $E^{k'}_{l,l',b}$: When decoding in block b the broadcast message index $z^{k'}_{l',b-l+l'+1}$ we assume that

$$\left(E_{0,b} \cup F_{[b-N;b-1]} \cup E^{[1;l']}_{l,b} \cup E^{[1;k'-1]}_{l,l',b}\right)^c \tag{50}$$

holds and we therefore know the message indices $q^{[1;l]}_{[l;N],b-l+l'+1}$, $q^{[1;m]}_{m\in[l'+1;l],b-l+l'+1}$, $z^{[1;\phi_m(l)]}_{m\in[l'+1;l],b-l+l'+1}$ and $z^{[1;k'-1]}_{l',b-l+l'+1}$. Using these indices we search for

$$\begin{aligned}\exists \tilde{z}^{k'}_{l',b-l+l'+1} : \Bigg(\mathrm{w}^{k'}_{l'}\left(\tilde{z}^{k'}_{l',b-l+l'+1}|z^{[1;k'-1]}_{l',b-l+l'+1}, q^{[1;l']}_{[l';N],b-l+l'+1}\right), \mathrm{y}_l(b-l+l'+1),\\ \mathbf{w}^{i\in[1;k'-1]}_{l'}, \mathbf{v}^{i\in[1;l']}_{l'}, \left\{\mathbf{v}^{[1;i]}_i, \mathbf{w}^{[1;\phi_i(l)]}_i : i \in [l'+1;l]\right\}, \mathbf{v}^{[1;l]}_{i\in[l;N]}\Bigg) \in \mathcal{A}^{*(n)}_\epsilon\end{aligned} \tag{51}$$

where we again dropped the block index $b-l+l'+1$ in the lower part for the sake of readability. If and only if n is sufficient large and

$$\hat{R}^{k'}_{l'} < \mathrm{I}\left(\mathrm{W}^{k'}_{l'};\mathrm{Y}_l|\mathrm{V}^{[1;l']}_{l'}, \mathrm{W}^{[1;k'-1]}_{l'}, \left\{\mathrm{V}^{[1;i]}_i, \mathrm{W}^{[1;\phi_i(l)]}_i : i \in [l'+1;l]\right\}, \mathrm{V}^{[1;l]}_{[l+1;N]}\right), \tag{52}$$

we can state that

$$\begin{aligned}\Pr\left\{E^{k'}_{l,l',b}|\left(E_{0,b} \cup F_{[1;b-1]} \cup E^{[1;l']}_{l,b} \cup E^{[1;k'-1]}_{l,l',b}\right)^c\right\} =\\ \Pr\left\{\tilde{z}^{k'}_{l',b-l+l'+1} \neq z^{k'}_{l',b-l+l'+1} \vee \text{ (51) is not satisfied}\right\} \leq \epsilon,\end{aligned} \tag{53}$$

and $\epsilon \to 0$. Eq. (53) follows from Lemma 1 and Corollary 1 with substitutions

$$\begin{aligned}&\mathrm{X} \mapsto \mathrm{W}^{k'}_{l'} &&\mathrm{U} \mapsto \left(\mathrm{W}^{[1;k'-1]}_{l'}, \mathrm{V}^{[1;l']}_{[l';N]}\right)\\ &\mathrm{Y} \mapsto \mathrm{Y}_l &&\mathrm{W} \mapsto \left(\mathbf{V}^{[l'+1;i]}_{i\in[l'+1;l-1]}, \mathrm{V}^{[l'+1;l]}_{[l;N]}, \mathbf{W}^{[1;\phi_i(l)]}_{i\in[l'+1;l-1]}, \mathrm{W}^{[1;M_l]}_l\right),\end{aligned}$$

as well as the fact that $F^c_{b-l+l'+1}$ implies $\tilde{z}^{k'}_{l',b-l+l'+1} = z^{k'}_{l',b-l+l'+1}$ if there is such a unique $\tilde{z}^{k'}_{l',b-l+l'+1}$.

3) Event $\hat{E}^{k'}_{l,l',b}$: When decoding $r^{k'}_{l',b-l+l'}$ we assume that

$$\left(E_{0,b} \cup F_{[b-N;b-1]} \cup E^{[1;k']}_{l,l',b} \cup \hat{E}^{[1;k'-1]}_{l,l',b} \cup E^{[1;l']}_{l,b} \cup \hat{E}^{[1;\phi_{j'}(l)]}_{l,j'\in[1;l'-1],b} \cup E^{[1;\phi_{j'}(l)]}_{l,j'\in[1;l'-1],b}\right)^c \tag{54}$$

holds, which implies that we know $z^{[1;k']}_{l',b-l+l'+1}$, $r^{[1;k'-1]}_{l',b-l+l'}$, $r^{[1;\phi_{j'}(l)]}_{j'\in[1;l'-1],b-l+j'}$, $q^{[1;l']}_{s,b-l+1}$, $z^{[1;\phi_{j'}(l)]}_{j'\in[1;l],b-l+1}$, $q^{[1;j']}_{j'\in[1;l],b-l+1}$ and $q^{[1;l]}_{[l+1;N],b-l+1}$. Using these message indices we build the intersection of $\mathcal{Q}^{k'}_{l,l',b}$ and $\mathcal{Z}^{k'}_{l'}(z^{k'}_{l',b-l+l'+1})$ as defined in (40) and (41). From $F^c_{[b-N;b-1]}$ we know that the correct quantization index is element of this set. The probability that (41) is satisfied can be given by

$$\Pr\left\{\hat{E}^{k'}_{l,l',b}|\left(E_{0,b} \cup F_{[b-N;b-1]} \cup E^{[1;k']}_{l,l',b} \cup \hat{E}^{[1;k'-1]}_{l,l',b} \cup E^{[1;l']}_{l,b} \cup \hat{E}^{[1;\phi_{j'}(l)]}_{l,j'\in[1;l'-1],b} \cup E^{[1;\phi_{j'}(l)]}_{l,j'\in[1;l'-1],b}\right)^c\right\} \leq \epsilon, \tag{55}$$

where $\epsilon \to 0$ iff n is sufficiently large and

$$\begin{aligned}\Delta_{l'}^{k'} - \Delta_{l'}^{k'-1} < \hat{R}_{l'}^{k'} + \mathrm{I}\Big(\hat{\mathrm{Y}}_{l'}^{k'}; \mathrm{Y}_l, \hat{\mathbf{Y}}_{i\in[1;k-2]}^{\phi_i(l)}, \Big\{\mathrm{V}_{[i;N]}^{i}, \mathrm{W}_i^{[1;\phi_i(l)]} : i \in [k;l]\Big\},\\ \mathbf{W}_{i\in[1;l']}^{[2;\phi_i(l)]}\Big|\hat{\mathrm{Y}}_{l'}^{k'-1}, \mathrm{U}_s^{[1;l']}, \Big\{\mathrm{V}_{[i;N]}^{i}, \mathrm{W}_i^{1} : i \in [1;l']\Big\}\Big)\end{aligned} \tag{56}$$

with $\Delta_{l'}^{0} = 0$. We applied in (56) Lemma 1 with substitutions

$$\begin{aligned}&\mathrm{X} \mapsto \hat{\mathrm{Y}}_{l'}^{k'} && \mathrm{U} \mapsto \Big(\hat{\mathrm{Y}}_{l'}^{[1;k'-1]}, \mathrm{U}_s^{[1;l']}, \Big\{\mathrm{V}_{[i;N]}^{i}, \mathrm{W}_i^{1} : i \in [1;l']\Big\}\Big)\\ &\mathrm{Y} \mapsto \Big(\mathrm{Y}_l, \hat{\mathbf{Y}}_{i\in[1;k-2]}^{\phi_i(l)}\Big) && \mathrm{W} \mapsto \Big\{\Big\{\mathrm{V}_i^{[1;i]}, \mathrm{W}_i^{[1;\phi_i(l)]} : i \in [1;l]\Big\}, \mathrm{V}_{[l+1;N]}^{[1;l]}\Big\} \setminus \mathrm{U},\end{aligned}$$

Using the Markov structure of the quantization messages and the chain rule of mutual information we can build the sum over the quantization rates to get

$$\begin{aligned}\Delta_{l'}^{k'} < \mathrm{I}\Big(\hat{\mathrm{Y}}_{l'}^{k'}; \mathrm{Y}_l, \hat{\mathbf{Y}}_{i\in[1;k-2]}^{\phi_i(l)}, \Big\{\mathrm{V}_{[i;N]}^{i}, \mathrm{W}_i^{[1;\phi_i(l)]} : i \in [k;l]\Big\},\\ \mathbf{W}_{i\in[1;l']}^{[2;\phi_i(l)]}|\mathrm{U}_s^{[1;l']}, \Big\{\mathrm{V}_{[i;N]}^{i}, \mathrm{W}_i^{1} : i \in [1;l']\Big\}\Big) + \sum_{i=1}^{k'} \hat{R}_{l'}^{i}\end{aligned}. \tag{57}$$

4) Event $E_{l,b}^{k}$: When decoding the source message index $q_{s,b-l+1}^{k}$, we assume that

$$\Big(E_{0,b} \cup F_{[b-N;b-1]} \cup E_{l,b}^{[1;k-1]} \cup \hat{E}_{l,l'\in[1;k-1],b}^{[1;\phi_{l'}(l)]} \cup E_{l,l'\in[1;k-1],b}^{[1;\phi_{l'}(l)]}\Big)^{c} \tag{58}$$

holds, which implies that the indices $q_{j\in\{0,[k;l-1]\},b-l+1+j}^{[1;k-1]}$, $z_{j'\in[j+1;l],b-l+1+j}^{[1;\phi_{j'}(l)]}$, $q_{j'\in[j+1;l],b-l+1+j}^{[1;j']}$, $q_{[l+1;N],b-l+1+j}^{[1;l]}$ and $r_{l'\in[1;k-1],b-l+l'}^{[1;\phi_{l'}(l)]}$ are known. According to (44) we must prove that the correct index $q_{s,b-l+1}^{k}$ is the only element of the intersection

$$\mathcal{T}_{l,b}^{k} = \mathcal{T}_{l,b,0}^{k} \cap \bigcap_{j=k}^{l-1} \mathcal{T}_{l,b,j}^{k}, \tag{59}$$

where $\mathcal{T}_{l,b,0}^{k}$ and $\mathcal{T}_{l,b,[k;l-1]}^{k}$ are defined in (42) and (43). From $F_{[b-N;b-1]}^{c}$ we know that the correct index will be element of each these sets. Using Lemma 1 the probability that a wrong index is element of one these sets is

$$\begin{aligned}&\Pr\left\{\tilde{q}_{j,b-l+1+j}^{k} \neq q_{j,b-l+1+j}^{k} \wedge \tilde{q}_{j,b-l+1+j}^{k} \in \mathcal{T}_{l,b,j}^{k}\right\} \doteq\\ &\qquad 2^{-n\left(\mathrm{I}\left(\mathrm{V}_j^{k};\mathrm{Y}_l|\mathrm{V}_j^{[1;k-1]},\left\{\mathrm{V}_i^{[1;i]},\mathrm{W}_i^{[1;\phi_i(l)]}:i\in[j+1;l]\right\},\mathbf{V}_{[l;N]}^{[1;l]}\right)\right)}\end{aligned} \tag{60}$$

and

$$\Pr\left\{\tilde{q}_{s,b-l+1}^{k} \neq q_{s,b-l+1}^{k} \wedge \tilde{q}_{s,b-l+1}^{k} \in \mathcal{T}_{l,b,0}^{k}\right\} \doteq 2^{-n\left(\mathrm{I}\left(\mathrm{U}_s^{k};\mathrm{Y}_l,\hat{\mathrm{Y}}_{l'\in[1;k-1]}^{\phi_{l'}(l)}|\mathrm{U}_s^{[1;k-1]},\left\{\mathrm{V}_{[i;N]}^{i},\mathrm{W}_i^{[1;\phi_i(l)]}:i\in[1;l]\right\}\right)\right)} \tag{61}$$

where $q_{s,b-l+1}^{k} = q_{j,b-l+1+j}^{k}$ as $F_{[b-N;b-1]}^{c}$ holds. From the independence of the used codebooks we know that

$$\begin{aligned}\Pr\left\{\tilde{q}_{s,b-l+1}^{k} \neq q_{s,b-l+1}^{k} \wedge \tilde{q}_{s,b-l+1}^{k} \in \mathcal{T}_{l,b}^{k}\right\} = \Pr\left\{\tilde{q}_{s,b-l+1}^{k} \neq q_{s,b-l+1}^{k} \wedge \tilde{q}_{s,b-l+1}^{k} \in \mathcal{T}_{l,b,0}^{k}\right\}\\ \cdot \prod_{j=k}^{l-1} \Pr\left\{\tilde{q}_{s,b-l+1}^{k} \neq q_{s,b-l+1}^{k} \wedge \tilde{q}_{s,b-l+1}^{k} \in \mathcal{T}_{l,b,j}^{k}\right\}.\end{aligned}$$

As there are $2^{nR_s^k}-1$ possible wrong indices it follows that

$$\begin{aligned} R_s^k <& \mathrm{I}\left(\mathrm{U}_s^k;\mathrm{Y}_l,\hat{\mathrm{Y}}_{l'\in[1;k-1]}^{\phi_{l'}(l)}|\mathrm{U}_s^{[1;k-1]},\left\{\mathrm{V}_{[i;N]}^i,\mathrm{W}_i^{[1;\phi_i(l)]}:i\in[1;l]\right\}\right)+\\ &\sum_{j=k}^{l-1}\mathrm{I}\left(\mathrm{V}_j^k;\mathrm{Y}_l|\mathrm{V}_j^{[1;k-1]},\left\{\mathrm{V}_i^{[1;i]},\mathrm{W}_i^{[1;\phi_i(l)]}:i\in[j+1;l]\right\},\mathbf{V}_{[l;N]}^{[1;l]}\right) \end{aligned} \tag{62}$$

must hold and $n\to\infty$ such that

$$\Pr\left\{E_{l,b}^k|\left(E_{0,b}\cup F_{[1;b-1]}\cup E_{l,b}^{[1;k-1]}\cup\hat{E}_{l,l'\in[1;k-1],b}^{[1;\phi_{l'}(l)]}\cup E_{l,l'\in[1;k-1],b}^{[1;\phi_{l'}(l)]}\right)^c\right\}\leq\epsilon, \tag{63}$$

with $\epsilon\to 0$.

5) Event $\hat{E}_{l,b}^k$: Before we build the quantization index $r_{l,b}^k$ we assume

$$\left(E_{0,b}\cup F_{[b-N;b-1]}\cup E_{l,b}^{[1;l]}\cup E_{l,b}^{[1;k-1]}\right)^c \tag{64}$$

which implies that $q_{s,b-l+1}^{[1;l]}$, $z_{[1;l],b-l+1}^1$, $q_{l'\in[1;l],b-l+1}^{[1;l']}$, $q_{l'\in[l+1;N],b-l+1}^{[1;l]}$ and $r_{l,b}^{[1;k-1]}$. are known. An error during the quantization occurs if (45) cannot be satisfied, hence we can state that

$$\Pr\left\{\hat{E}_{l,b}^k|F_{[1;b-1]}^c\cap\hat{E}_{l,b}^{[1;k-1],c}\cap E_{l,b}^{[1;l],c}\cap\hat{E}_{l,j'\in[1;l-1],b}^{[1;\phi_{j'}(l)],c}\cap E_{l,j'\in[1;l-1],b}^{[1;\phi_{j'}(l)],c}\right\}\leq\epsilon. \tag{65}$$

with $\epsilon\to 0$ iff $n\to\infty$ and

$$\Delta_l^j-\Delta_l^{j-1} > \mathrm{I}\left(\hat{\mathrm{Y}}_l^j;\mathrm{Y}_l|\hat{\mathrm{Y}}_l^{j-1},\mathrm{U}_s^{[1;l]},\left\{\mathrm{V}_{[i;N]}^i,\mathrm{W}_i^1:i\in[1;l]\right\}\right) \tag{66}$$

$$\Delta_l^j > \mathrm{I}\left(\hat{\mathrm{Y}}_l^j;\mathrm{Y}_l|\mathrm{U}_s^{[1;l]},\left\{\mathrm{V}_{[i;N]}^i,\mathrm{W}_i^1:i\in[1;l]\right\}\right) \tag{67}$$

which results from the rate distortion theorem [11, Theorem 13.2.1], the chain rule for mutual information as well as the previously discussed Markov structure within the quantizations. Using (57) we can state for the quantization source coding rates

$$\begin{aligned} \sum_{i=1}^m\hat{R}_l^i=R_{\mathrm{Y}_l|\cdot}^{\mathrm{WZ}}(D_l^m)>\max_{\substack{j\in[m;M_l]\\ j'=o_l(j)}}\Big[\Delta_l^m-\mathrm{I}\Big(\hat{\mathrm{Y}}_l^m;\mathrm{Y}_{j'},\hat{\mathbf{Y}}_{i\in[1;l-1]}^{\phi_i(j')},\left\{\mathrm{V}_{[i;N]}^i,\mathrm{W}_i^{[1;\phi_i(l)]}:i\in[l+1;j']\right\},\\ \mathbf{W}_{i\in[1;l]}^{[2;\phi_i(j')]}|\mathrm{U}_s^{[1;l]},\left\{\mathrm{V}_{[i;N]}^i,\mathrm{W}_i^1:i\in[1;l]\right\}\Big],m\in[1;M_l]. \end{aligned} \tag{68}$$

If we use (67) in (68) it follows that

$$\begin{aligned} \sum_{i=1}^m\hat{R}_l^i=\max_{\substack{j\in[m;M_l]\\ j'=o_l(j)}}\Big[\mathrm{I}\left(\hat{\mathrm{Y}}_l^m;\mathrm{Y}_l|\mathrm{U}_s^{[1;l]},\left\{\mathrm{V}_{[i;N]}^i,\mathrm{W}_i^1:i\in[1;l]\right\}\right)-\mathrm{I}\Big(\hat{\mathrm{Y}}_l^m;\mathrm{Y}_{j'},\hat{\mathbf{Y}}_{i\in[1;l-1]}^{\phi_i(j')},\\ \left\{\mathrm{V}_{[i;N]}^i,\mathrm{W}_i^{[1;\phi_i(l)]}:i\in[l+1;j']\right\},\mathbf{W}_{i\in[1;l]}^{[2;\phi_i(j')]}|\mathrm{U}_s^{[1;l]},\left\{\mathrm{V}_{[i;N]}^i,\mathrm{W}_i^1:i\in[1;l]\right\}\Big] \end{aligned} \tag{69}$$

Consider now the following mapping

$$\begin{aligned} &\mathrm{W}\mapsto\left\{\mathrm{V}_{[i;N]}^i,\mathrm{W}_i^{[1;\phi_i(j')]}:i\in[l+1;j']\right\},\mathbf{W}_{i\in[1;l]}^{[2;\phi_i(j')]}, && \mathrm{Y}\mapsto\left(\mathrm{Y}_{j'},\hat{\mathbf{Y}}_{i\in[1;l-1]}^{\phi_i(j')}\right)\\ &\mathrm{U}\mapsto\left(\mathrm{U}_s^{[1;l]},\left\{\mathrm{V}_{[i;N]}^i,\mathrm{W}_i^1:i\in[1;l]\right\}\right), && \mathrm{X}\mapsto\hat{\mathrm{Y}}_l^m. \end{aligned}$$

Due to the Markov chain $\hat{\mathrm{X}} \leftrightarrow (\mathrm{Y}_l, \mathrm{U}) \leftrightarrow (\mathrm{Y}, \mathrm{W})$ it follows that $\mathrm{H}\left(\hat{\mathrm{X}}|\mathrm{Y}_l, \mathrm{U}\right) = \mathrm{H}\left(\hat{\mathrm{X}}|\mathrm{Y}_l, \mathrm{Y}, \mathrm{W}, \mathrm{U}\right)$ which gives

$$\begin{aligned}\mathrm{I}\left(\hat{\mathrm{X}}; \mathrm{Y}_l|\mathrm{U}\right) - \mathrm{I}\left(\hat{\mathrm{X}}; \mathrm{Y}, \mathrm{W}|\mathrm{U}\right) &= \mathrm{H}\left(\hat{\mathrm{X}}|\mathrm{U}\right) - \mathrm{H}\left(\hat{\mathrm{X}}|\mathrm{U}\right) - \mathrm{H}\left(\hat{\mathrm{X}}|\mathrm{Y}_l, \mathrm{U}\right) + \mathrm{H}\left(\hat{\mathrm{X}}|\mathrm{Y}, \mathrm{W}, \mathrm{U}\right) \\ &= \mathrm{I}\left(\hat{\mathrm{X}}; \mathrm{Y}_l|\mathrm{Y}, \mathrm{W}, \mathrm{U}\right).\end{aligned}$$

Applying this result to (69) we have

$$\sum_{i=1}^{m} \hat{R}_l^i = \max_{\substack{j\in[m;M_l] \\ j'=o_l(j)}} \mathrm{I}\Big(\hat{\mathrm{Y}}_l^m; \mathrm{Y}_l|\mathrm{Y}_{j'}, \hat{\mathbf{Y}}_{i\in[1;l-1]}^{\phi_i(j')}, \mathrm{U}_s^{[1;l]}, \Big\{\mathrm{V}_{[i;N]}^i, \mathrm{W}_i^{[1;\phi_i(j')]} : i \in [1; j']\Big\}\Big). \tag{70}$$

F. Bringing all together

The previous events were necessary to prove the error in block b. As we are interested in the overall error probability after B blocks, we need to consider the overall error probability P_e using standard techniques:

$$P_e \leq \Pr\left\{\bigcup_{b=1}^{B} F_b\right\} \leq \sum_{b=1}^{B} \Pr\left\{F_b \cap F_{[1;b-1]}^c\right\}. \tag{71}$$

Using the definition of F_b in (46) we get

$$\Pr\left\{F_b \cap F_{[1;b-1]}^c\right\} = \Pr\left\{E_{0,b} \cup \bigcup_{l=1}^{N+1} \left(\bigcup_{k=1}^{l-1} E_{l,b}^k \cup \bigcup_{l'=1}^{l-1} \bigcup_{k'=1}^{\phi_{l'}(l)} \left(E_{l,l',b}^{k'} \cup \hat{E}_{l,l',b}^{k'}\right) \cup \bigcup_{k'=1}^{M_l} \hat{E}_{l,b}^{k'}\right) \cap F_{[1;b-1]}^c\right\} \tag{72}$$

$$\leq (49) + \sum_{l=1}^{N} \left(\sum_{k=1}^{l-1} (63) + \sum_{l'=1}^{l-1} \sum_{k'=1}^{\phi_{l'}(l)} [(53) + (55)] + \sum_{k'=1}^{M_l} (65)\right). \tag{73}$$

Using this result in (71) we have

$$P_e \leq B\left(1 + N\left(2N + N^2\right)\right)\epsilon, \tag{74}$$

which can be made arbitrarily small as n grows to infinity. Now lets apply the standard random coding argument by throwing away the worse half of codewords. It follows for the overall rate

$$\tilde{R} = \frac{nR(B-N) - 1}{nB}, \tag{75}$$

which approaches R as $n \to \infty$ and then $B \to \infty$. This and the previously given bounds prove that R in Theorem 1 is achievable with arbitrarily low probability of error.

APPENDIX II

PROOF OF THEOREM 2

In order to prove Theorem 2, we apply in this section Theorem 1 to the complex Gaussian multiple relay network presented in Section IV.

- **Rates on source messages:** Reconsider the source rate constraints given in (4) for the DMC. Now it follows for $\mathrm{I}\left(\mathrm{V}_N^j;\mathrm{Y}_d|\mathrm{V}_N^{[1;j-1]}\right)$:

$$\mathrm{I}\left(\mathrm{V}_N^j;\mathrm{Y}_d|\mathrm{V}_N^{[1;j-1]}\right) = \mathrm{h}\left(\mathrm{Y}_d|\mathrm{V}_N^{[1;j-1]}\right) - \mathrm{h}\left(\mathrm{Y}_d|\mathrm{V}_N^{[1;j]}\right), j\in[1;N] \tag{76}$$

$$\begin{aligned} &= \mathrm{h}\left(\sum_{l=0}^{N} h_{l,d}\mathrm{X}_{l;b} + \mathrm{Z}_{d;b} - \sum_{k=1}^{j-1}\left(h_{s,d}\sqrt{\alpha_{s,N}^k P_s} + \sum_{l=k}^{N} h_{l,d}\sqrt{\alpha_{l,N}^k P_l}\right)\mathrm{V}_{N;b}^k\right) - \\ &\quad \mathrm{h}\left(\sum_{l=0}^{N} h_{l,d}\mathrm{X}_{l;b} + \mathrm{Z}_{d;b} - \sum_{k=1}^{j}\left(h_{s,d}\sqrt{\alpha_{s,N}^k P_s} + \sum_{l=k}^{N} h_{l,d}\sqrt{\alpha_{l,N}^k P_l}\right)\mathrm{V}_{N;b}^k\right) \end{aligned} \tag{77}$$

with the differential entropy [11, Eq. (9.34)]

$$\mathrm{h}\left(\mathrm{X} = (\mathrm{X}_1,\ldots,\mathrm{X}_n)\right) = \log\left((2\pi e)^n \det \mathbf{K}_{\mathrm{X}}\right), \tag{78}$$

and $\mathbf{K}_{\mathrm{X}}$ being the covariance matrix of the multivariate Gaussian r.v. X. Now reconsider the definitions in (11), (12) and (15) for $\Gamma_{l,l'}^k$ and $\Lambda_l^{k,k'}$, respectively. With these definitions it follows

$$\mathrm{I}\left(\mathrm{V}_N^j;\mathrm{Y}_d|\mathrm{V}_N^{[1;j-1]}\right) = \log\left(\frac{\sum\limits_{l=1}^{N}\left(h_{l,d}^2\beta_l^{[1;M_l]}P_l + \sum\limits_{k=1}^{l}\Gamma_{l,d}^k\right) + h_{s,d}^2\alpha_{s,s}^{[1;N+1]}P_s + N_d - \sum\limits_{k=1}^{j-1}\Gamma_{N,d}^k}{\sum\limits_{l=1}^{N}\left(h_{l,d}^2\beta_l^{[1;M_l]}P_l + \sum\limits_{k=1}^{l}\Gamma_{l,d}^k\right) + h_{s,d}^2\alpha_{s,s}^{[1;N+1]}P_s + N_d - \sum\limits_{k=1}^{j}\Gamma_{N,d}^k}\right) \tag{79}$$

$$= \mathrm{C}\left(\frac{\Gamma_{N,d}^j}{\mathbf{\Gamma}_{l\in[1;N-1],d}^{[1;l]} + \mathbf{\Gamma}_{N,d}^{[j+1;N]} + \Lambda_d^{d,d} + \Gamma_{s,d}^{[1;N+1]} + N_d}\right) \tag{80}$$

with the capacity function $\mathrm{C}(x) = \log(1+x)$. In a similar way we can show

$$\begin{aligned} &\mathrm{I}\left(\mathrm{V}_l^j;\mathrm{Y}_{l+k}|\mathrm{V}_l^{[1;j-1]}, \left\{\mathrm{V}_i^{[1;i]}, \mathrm{W}_i^{[1;\phi_i(l+k)]} : i\in[l+1;l+k]\right\}, \mathrm{V}_{[l+k+1;N]}^{[1;l+k]}\right) \\ &\quad < \mathrm{C}\left(\frac{\Gamma_{l,l+k}^j}{\mathbf{\Gamma}_{l'\in[1;l-1],l+k}^{[1;l']} + \Gamma_{l,l+k}^{[j+1;l]} + \Gamma_{l'\in[l+k+1;N],l+k}^{[l+k+1;l']} + \Lambda_{l+k}^{l+1,l+k} + \Gamma_{s,l+k}^{[1;N+1]} + N_{l+k}}\right), \\ &\qquad l\in[1;N-1], j\in[1;l], k\in[1;N-l+1]. \end{aligned} \tag{81}$$

Finally, reconsider the definitions in (13), (14) and (16)-(19) which are used to derive the first term in (4):

$$\mathrm{I}\left(\mathrm{U}_s^j;\mathrm{Y}_k,\hat{\mathbf{Y}}_{i\in[1;j-1]}^{\phi_i(k)}|\mathrm{U}_s^{[1;j-1]}, \left\{\mathrm{V}_{[i;N]}^i, \mathrm{W}_i^{[1;\phi_i(k)]} : i\in[1;k]\right\}\right) = \tag{82}$$

$$\mathrm{h}\left(\mathrm{Y}_k,\hat{\mathbf{Y}}_{i\in[1;j-1]}^{\phi_i(k)}|\mathrm{U}_s^{[1;j-1]}, \left\{\mathrm{V}_{[i;N]}^i, \mathrm{W}_i^{[1;\phi_i(k)]} : i\in[1;k]\right\}\right) - \tag{83}$$

$$\mathrm{h}\left(\mathrm{Y}_k,\hat{\mathbf{Y}}_{i\in[1;j-1]}^{\phi_i(k)}|\mathrm{U}_s^{[1;j]}, \left\{\mathrm{V}_{[i;N]}^i, \mathrm{W}_i^{[1;\phi_i(k)]} : i\in[1;k]\right\}\right) \tag{84}$$

$$= \log\left((2\pi e)^j \det K_{s,k}^{j-1,j-1}\right) - \log\left((2\pi e)^j \det K_{s,k}^{j-1,j}\right) \tag{85}$$

$$= \log\left(\frac{\det K_{s,k}^{j-1,j-1}}{\det K_{s,k}^{j-1,j}}\right). \tag{86}$$

Now it follows for the source rates R_s^k using the previous results:

$$R_s^k < \min_{l\in[k;N+1]} \log\left(\frac{\det K_{s,l}^{k-1,k-1}}{\det K_{s,l}^{k-1,k}}\right) + \sum_{j=k}^{l-1} \mathrm{C}\left(\frac{\Gamma_{j,l}^k}{\mathbf{\Gamma}^{[1;l']}_{l'\in[1;j-1],l} + \Gamma_{j,l}^{[k+1;j]} + \Gamma^{[l+1;l']}_{l'\in[l+1;N],l} + \Lambda_l^{j+1,l} + \Gamma_{s,l}^{[1;N+1]} + N_l}\right). \tag{87}$$

- **Rates on broadcast messages:** Using the previous description it is immediately possible to state for the broadcast message constraints in (5):

$$\hat{R}_l^j < \min_{\substack{k\in[j;M_l]\\ k'=o_l(k)}} \mathrm{C}\left(\frac{h_{l,k'}^2\beta_l^j P_l}{\mathbf{\Gamma}^{[1;l']}_{l'\in[1;l-1],k'} + \Gamma^{[k'+1;l']}_{l'\in[k'+1;N],k'} + \Lambda_{k'}^{l+1,k'} - h_{l,k'}^2\sum_{i=1}^{j}\beta_l^i P_l + \Gamma_{s,k'}^{[1;N+1]} + N_{k'}}\right), \tag{88}$$

$$l\in[1;N+1], j\in[1;M_l].$$

- **Rates on successive refinement conditions:** Reconsider the necessary side condition on the successive refinement conditions given in (6). We can significantly simplify this condition to

$$\sum_{i=1}^{m}\hat{R}_l^i > \max_{\substack{j\in[m;M_l]\\ j'=o_l(j)}} \mathrm{I}\Big(\hat{\mathrm{Y}}_l^m;\mathrm{Y}_l|\mathrm{Y}_{j'},\mathrm{U}_s^{[1;l]},\Big\{\mathrm{V}^i_{[i;N]},\mathrm{W}_i^{[1;\phi_i(j')]} : i\in[1;j']\Big\}\Big), l\in[1;N], m\in[1;M_l], \tag{89}$$

which is a result of the following inequality

$$\begin{aligned}
\mathrm{I}\left(\hat{\mathrm{X}};\mathrm{Y}_l|\mathrm{Y}_{j'},\mathrm{Y},\mathrm{W},\mathrm{U}\right) &\overset{(a)}{=} \mathrm{I}\left(\hat{\mathrm{X}};\mathrm{Y}_l|\mathrm{U}\right) - \mathrm{I}\left(\hat{\mathrm{X}};\mathrm{Y}_{j'},\mathrm{Y},\mathrm{W}|\mathrm{U}\right) &(90)\\
&\overset{(b)}{=} \mathrm{I}\left(\hat{\mathrm{X}};\mathrm{Y}_l|\mathrm{U}\right) - \mathrm{I}\left(\hat{\mathrm{X}};\mathrm{Y}_{j'},\mathrm{W}|\mathrm{U}\right) - \underbrace{\mathrm{I}\left(\hat{\mathrm{X}};\mathrm{Y}|\mathrm{Y}_{j'},\mathrm{W},\mathrm{U}\right)}_{\geq 0} &(91)\\
&\overset{(c)}{\leq} \mathrm{I}\left(\hat{\mathrm{X}};\mathrm{Y}_l|\mathrm{Y}_{j'},\mathrm{W},\mathrm{U}\right) &(92)
\end{aligned}$$

with the mappings

$$\begin{aligned}
&\mathrm{W}\mapsto\left\{\mathrm{V}^i_{[i;N]},\mathrm{W}_i^{[1;\phi_i(j')]} : i\in[l+1;j']\right\}, \mathbf{W}^{[2;\phi_i(j')]}_{i\in[1;l]}, &&\mathrm{Y}\mapsto\hat{\mathbf{Y}}^{\phi_i(j')}_{i\in[1;l-1]},\\
&\mathrm{U}\mapsto\left(\mathrm{U}_s^{[1;l]},\left\{\mathrm{V}^i_{[i;N]},\mathrm{W}_i^1 : i\in[1;l]\right\}\right), &&\mathrm{X}\mapsto\hat{\mathrm{Y}}_l^m.
\end{aligned}$$

Furthermore, (a) and (c) follow the arguments already applied in (69) and (b) uses the chain rule for mutual information. Let us again use the previous mappings and consider the following equalities:

$$\begin{aligned}
\mathrm{I}\left(\hat{\mathrm{X}};\mathrm{Y}_l|\mathrm{Y}_{j'},\mathrm{W},\mathrm{U}\right) &= \mathrm{h}\left(\hat{\mathrm{Y}}_l^m|\mathrm{Y}_{j'},\mathrm{U},\mathrm{W}\right) - \mathrm{h}\left(\hat{\mathrm{Y}}_l^m|\mathrm{Y}_l,\mathrm{Y}_{j'},\mathrm{U},\mathrm{W}\right) &(93)\\
&\overset{(a)}{=} \mathrm{h}\left(\hat{\mathrm{Y}}_l^m|\mathrm{Y}_{j'},\mathrm{U},\mathrm{W}\right) - \mathrm{h}\left(\hat{\mathrm{Y}}_l^m|\mathrm{Y}_l,\mathrm{U}\right) &(94)\\
&= \mathrm{h}\left(\hat{\mathrm{Y}}_l^m,\mathrm{Y}_{j'}|\mathrm{U},\mathrm{W}\right) - \mathrm{h}\left(\mathrm{Y}_{j'}|\mathrm{U},\mathrm{W}\right) - \mathrm{h}\left(\hat{\mathrm{Y}}_l^m|\mathrm{Y}_l,\mathrm{U}\right), &(95)
\end{aligned}$$

where (a) exploits the Markov chain $\mathrm{Y}_l^m \leftrightarrow (\mathrm{Y}_l, \mathrm{U}) \leftrightarrow (\mathrm{Y}_{j'}, \mathrm{W})$. The third term in (95) is given by

$$\begin{aligned} \mathrm{h}\left(\hat{\mathrm{Y}}_l^m | \mathrm{Y}_l, \mathrm{U}\right) &= \mathrm{h}\left(\mathrm{Y}_{l;b} + \sum_{i=m}^{M_l} Z_{l;b}^i | \mathrm{Y}_{l;b}, \mathrm{U}\right) && (96) \\ &= \log\left(2\pi e \sum_{i=m}^{M_l} N_l^i\right). && (97) \end{aligned}$$

The second term in (95) is given in the same way by

$$\mathrm{h}\left(\mathrm{Y}_{j'} | \mathrm{U}, \mathrm{W}\right) = \log\left(2\pi e \left(\Gamma_{l' \in [j'+1;N], j'}^{[j'+1;l']} + \Gamma_{s,j'}^{[l+1;N+1]} + \Lambda_{j'}^{1,j'} + N_{j'}\right)\right). \tag{98}$$

Finally, the first term in (95) is given by

$$\mathrm{h}\left(\hat{\mathrm{Y}}_l^m, \mathrm{Y}_{j'} | \mathrm{U}, \mathrm{W}\right) = \log\left((2\pi e)^2 \det \mathbf{K}_{l,j'}^m\right), \tag{99}$$

with the covariance matrix $\mathbf{K}_{l,j'}^m$ given by

$$\begin{aligned} \left[\mathbf{K}_{l,j'}^m\right]_{1,1} =& \mathrm{Var}\left(\hat{\mathrm{Y}}_l^m | \mathrm{U}, \mathrm{W}\right) = \Gamma_{l' \in [j'+1;N], l}^{[j'+1;l']} + \Gamma_{s,l}^{[l+1;N+1]} + \Lambda_l^{1,j'} + N_l + \sum_{i=m}^{M_l} N_l^i && (100) \\ \left[\mathbf{K}_{l,j'}^m\right]_{2,2} =& \mathrm{Var}\left(\mathrm{Y}_{j'} | \mathrm{U}, \mathrm{W}\right) = \Gamma_{l' \in [j'+1;N], j'}^{[j'+1;l']} + \Gamma_{s,j'}^{[l+1;N+1]} + \Lambda_{j'}^{1,j'} + N_{j'} && (101) \\ \left[\mathbf{K}_{l,j'}^m\right]_{1,2} =& \mathrm{Cov}\left(\hat{\mathrm{Y}}_l^m | \mathrm{U}, \mathrm{W}; \mathrm{Y}_{j'} | \mathrm{U}, \mathrm{W}\right) = \tilde{\Gamma}_{l' \in [j'+1;N], j', l}^{[j'+1;l']} + \tilde{\Gamma}_{s,j',l}^{[l+1;N+1]}, && (102) \end{aligned}$$

where we used the definitions given in (13) and (14) for $\tilde{\Gamma}_{l,m,m'}^k$. Finally, using (97)-(99) in (89) it follows that

$$\sum_{i=1}^{m} \hat{R}_l^i > \max_{\substack{j \in [m;M_l] \\ j' = o_l(j)}} \log\left(\frac{\det K_{l,j'}^m}{\left(\sum\limits_{i=m}^{M_l} N_l^i\right) \cdot \left(\Gamma_{l' \in [j'+1;N], j'}^{[j'+1;l']} + \Gamma_{s,j'}^{[l+1;N+1]} + \Lambda_{j'}^{1,j'} + N_{j'}\right)}\right). \tag{103}$$

Since determinant of $\mathbf{K}_{l,j'}^m$ is given by

$$\det K_{l,j'}^m = \mathrm{Var}\left(\hat{\mathrm{Y}}_l^m | \mathrm{U}, \mathrm{W}\right) \mathrm{Var}\left(\mathrm{Y}_{j'} | \mathrm{U}, \mathrm{W}\right) - \mathrm{Cov}\left(\hat{\mathrm{Y}}_l^m | \mathrm{U}, \mathrm{W}; \mathrm{Y}_{j'} | \mathrm{U}, \mathrm{W}\right)^2, \tag{104}$$

it follows for (103):

$$\begin{aligned} \sum_{i=1}^{m} \hat{R}_l^i > \max_{\substack{j \in [m;M_l] \\ j' = o_l(j)}} = \mathrm{C}\Bigg(& \frac{\Gamma_{l' \in [j'+1;N], l}^{[j'+1;l']} + \Gamma_{s,l}^{[l+1;N+1]} + \Lambda_l^{1,j'} + N_l}{\sum\limits_{i=m}^{M_l} N_l^i} - \\ & \frac{\left(\tilde{\Gamma}_{l' \in [j'+1;N], j', l}^{[j'+1;l']} + \tilde{\Gamma}_{s,j',l}^{[l+1;N+1]}\right)^2}{\left(\sum\limits_{i=m}^{M_l} N_l^i\right) \cdot \left(\Gamma_{l' \in [j'+1;N], j'}^{[j'+1;l']} + \Gamma_{s,j'}^{[l+1;N+1]} + \Lambda_{j'}^{1,j'} + N_{j'}\right)}\Bigg) \end{aligned} \tag{105}$$

Using (105) we get the constraints on the quantization noise variance given in (23).
